Abstract

This paper is a summary of analysis work completed during phase 2 of the National Institute of Standards and Technology's (NIST) Process Specification Language (PSL) project. A set of requirements for this language was produced in phase 1. These requirements were divided into separate categories. The main categories of interest for this analysis are the core and outer core requirements. Each set was then further partitioned into either representational or functional requirements. In phase 2, existing candidate process representations were proposed which were believed to satisfy much of the representational and functional needs. Most of the particular set of candidates reviewed are those representations generated by participants in the DARPA/Rome Laboratory Planning Initiative (ARPI), or representations in which participants in the initiative played a part. The results of the analyses of a number of the candidate representations with respect to the requirements are reviewed here.

^{*}With contributions from PSL working group members which are specifically credited in the paper where provided.

1 Introduction

The National Institute of Standards and Technology's (NIST) Process Specification Language (PSL) project [Schlenoff *et al.* 96] grew out of a need for a shared process representation in a manufacturing environment. The project members have summarised their goal as

"... to create a process representation that is common to all manufacturing applications, generic enough to be decoupled from any given application, and robust enough to be able to represent the necessary process information for any given application. This representation would facilitate communication between the various applications because they would all speak the same language" [Schlenoff *et al.* 96]

While the motivation was primarily from a manufacturing perspective, the project also recognised that this "shared representation" should apply to a broad range of systems and uses including: project management, business process reengineering, workflow management, process planning, and production scheduling. In addition to the NIST core project members, a number of individuals from academia, governmental and industrial organisations were assembled to assist in the effort. Steve Polyak and Austin Tate from the O-Plan project at the University of Edinburgh are participants in the NIST PSL project.

The project set out to achieve its goal through a series of phases that structured the work. During phase 1, a set of requirements were developed that were expected to be satisfied by the end-product language [Schlenoff *et al.* 96, Gruninger *et al.* 97]. In phase 2, a variety of existing representations were identified that could address the requirements to some degree. A number of participants performed analyses of various representations relative to the specified requirements. This paper is a summary of the analysis work completed by the authors¹ during 12/96 - 3/97 for phase 2 of the project.

Section 2 takes a look at the PSL project in more detail. A summary of the representations we examined and some of our reasons for including them are outlined in section 3. The result of the analysis is presented in section 4 which is then discussed in more depth in section 5. Finally, we review some conclusions of this work in section 6.

2 Process Specification Language

2.1 Mission

NIST's mission is to promote U.S. economic growth by working with industry to develop and apply technology and standards. One of the working areas involves the development of standards for the manufacturing industry. There exists an identified need within the manufacturing industry for a standard representation of processes and process information. The NIST Process Specification Language (PSL) is being developed as an interlingua representation that can be used for sharing process knowledge within a manufacturing environment.

2.2 Phase 1

In the initial phase of this work, a set of requirements were gathered by inspecting a number of applications which utilise process knowledge [Schlenoff *et al.* 96]. These requirements were categorised into: core, outer core, plug-in, and application-specific groupings. The analysis in this paper is only concerned with the first two categories. The core reflects those requirements that the PSL group concluded were either essential, critical, or typically common for all of their identified uses of process knowledge. The outer core contains requirements which are considered to be "pervasive" but not necessarily essential. The core and outer core are further sub-divided into either representational or functional requirements.

¹With the exception of the OMWG CPR analysis, which was completed by Adam Pease at Teknowledge, Inc. and the PIF analysis which was jointly produced by the authors and other members of the PIF working group.

2.3 Phase 2

The approach for phase 2 was to identify existing representations that were believed to address these requirements. Each representation was then assessed by assigning an evaluation of its coverage for each requirement in the core and outer core. The possible values for each requirement were: completely satisfies, partially satisfies, cannot satisfy, or uncertain. Analysts were also asked to provide comments and/or describe constructs that supported their rating for each entry.

3 Candidate Representations

As mentioned in the previous section, a number of candidate representations were identified by various PSL members based on the phase 1 requirements. The idea was to provide an overall picture of how existing representations addressed various process/plan requirements in a number of ways. Candidates that were "strong" in certain areas might suggest good representational approaches to consider. With one exception, the representations offered and their corresponding analyses shown here were influenced strongly by the authors' knowledge and experience with DARPA/Rome Laboratory Planning Initiative (ARPI) or other DARPA-funded plan, process, and schedule representations. The exception representational analysis was ISO's STEP Part 49 for which the anlysis was performed as a validation check of another analysis and the overall approach. These representations are summarised below.

3.1 ACT

Traditionally, plan generation and reactive execution have been considered as separate activities, with few attempts to integrate them within a single system. The ACT formalism [Wilkins & Myers 95] is a language for representing the knowledge required to support both the generation of complex plans and reactive execution of those plans in dynamic environments. ACT has been used as the interlingua in an implemented system that links a previously implemented planner (SIPE-2) with a previously implemented executor (PRS).

ACT is intended to serve as a general-purpose representation language that could be used to share knowledge between many different execution and planning systems. The representational and computational adequacy of ACT has been validated by implementing the Cypress system, which uses ACT as an interlingua to enable runtime interactions between planning and execution subsystems. ACT focuses on a practical, yet sufficiently expressive representation that can address a variety of needs. Sample domains that ACT has been used in include: controlling an indoor mobile robot, and military operations planning.

The ACT formalism is a domain-independent language for representing the kinds of knowledge about activity used by both plan generation and reactive execution systems. The basic unit of representation is an Act, which can be used to encode both plan fragments and standard operating procedures (SOPs). An Act describes a set of actions that can be taken to fulfill some designated purpose under certain conditions. The purpose could be either to satisfy a goal or to respond to some event in the world. The purpose and applicability criteria for an Act are formulated using a fixed set of environment conditions. Action specifications are called the plot, and consists of a partially ordered set of actions and subgoals. The environment conditions and plots are specified using goal expressions, each of which consists of one of a predefined set of meta-predicates applied to a logical formula. The meta-predicates permit the specification of many different modes of activity, including goals of achievement, maintenance, and testing. ACT can be used to build a very strong model of the relationships between actions, temporal requirements, and resources. It has been shown to have expressive and computational adequacy in several applications. Specific manufacturing elements would need to be added as extensions to support these domain-specific requirements.

ACT has been used as the common representation for SIPE-2 and PRS in SRI's Cypress system [Wilkins *et al.* 95]². SIPE-2 was also used as the core reasoning engine in SRI's SOCAP (System for Oper-

 $^{^{2}}Cypress = SIPE + PRS$

ations Crisis Action Planning) [Wilkins & Desimone 94], which was part of the second Integrated Feasibility Demonstration of ARPI [Fowler *et al.* 96].

3.2 CPR

The DARPA-sponsored Object Model Working Group is currently developing a "core plan representation" (CPR) [Pease & Carrico 97] which is aimed at supporting the representational needs of many types of planning systems. The OMWG's stated goal is

"...to leverage common functionality and facilitate the reuse and sharing of information between a variety of planning and control systems" [Pease & Carrico 97]

CPR has utilised ARPI work on $KRSL^3$ [Lehrer(ed.) 93], the POCG⁴, the O-Plan project [Currie & Tate 91], and the <I-N-OVA> representation (see below). CPR is composed of a set of basic plan concepts that have been assembled into a refined design framework. The initial minimal set of concepts included Action, Resource, Actor, and Objective. This set was then: expanded with more entities (e.g. Plan, TimePoint, etc.), defined with individual properties (e.g. an Actor has an Objectives slot, etc.) and structured with stated relations (e.g. a Plan contains Actions, Actions contain TimePoints, etc.)

CPR's intended application might involve the Joint Task Force Advanced Technology Demonstration (JTF-ATD) and Joint Forces Air Component Commander (JFACC) programs which are two DARPA joint force military planning applications. The OMWG has also identified the possibility of applying CPR to non-military applications as well.

3.3 < I-N-OVA >

<I-N-OVA> [Tate 96c, Tate 96b, Tate 97] is a constraint model of tasks, plans, processes, and activities which adopts the perspective that all of these sources are "constraints on behaviour". This model can be used as an ontology for shared representations amongst various operations in the planning and execution process including: knowledge acquisition, formal analysis, user communication, and system manipulation.

The acronym, <I-N-OVA> stands for: Issues; Nodes; and Ordering, Variable, and Auxiliary constraints. Issues and nodes are also expressed as constraints and can be thought of as implied constraints and activity constraints, respectively. The inclusion of "issues" in the specification of a plan or process is unique and allows the "state" of the planning process to be captured and communicated throughout the life-cycle of a plan. Tate relates these various constraint types together by stating

"Planning is the taking of planning decisions (I) which selects the activities to perform (N) which creates, modifies or uses the plan objects or products (V) in the correct time (O) within the authority, resources and other constraints specified (A)."⁵

<I-N-OVA> is not a representation language like some of the other candidates discussed in this paper (e.g. ACT, O-Plan TF). Rather, it is a conceptual model which can underly languages which describe activities, plans and processes. O-Plan's widely used domain description language (TF) can be seen as an implementation that rests upon the more general <I-N-OVA> model. The different types of constraints in the <I-N-OVA> model reflect the different types of components in an O-Plan agent (issue controller, issue handlers, and plug-in constraint managers) [Tate *et al.* 96].

³KRSL - Knowledge Representation Source Language

⁴POCG - Planning Ontology Construction Group, See Appendix in [Tate 96c]

⁵See <I-N-OVA> rationale at http://www.aiai.ed.ac.uk/~oplan/inova.html

3.4 OZONE

OZONE [Smith & Becker 97] is a toolkit for configuring constraint-based scheduling systems ⁶. A central component of OZONE is its scheduling ontology, which defines a reusable and extensible base of concepts for describing and representing scheduling problems, domains and constraints.

It had been noticed that there is commonality in scheduling system requirements and design at several levels across application domains. Many of the concepts in the problems, domain and constraints could be considered to be reusable and extensible. The OZONE ontology provides a framework for analysing the information requirements of a given target domain, and a structural foundation for constructing an appropriate domain model. Through direct association of software component capabilities with concepts in the ontology, the ontology promotes rapid configuration of executable systems and allows concentration of modelling effort on those idiosyncratic aspects of the target domain. The OZONE ontology and toolkit represent a synthesis of extensive prior work in developing constraint-based scheduling models for a range of applications in manufacturing, space and transportation logistics.

OZONE adopts an activity-centred modelling viewpoint. There are five basic concepts of the ontology -Demand, Activity, Resource, Product, and Constraint. The ontology also defines specific inter-relationships and properties for these entities.Scheduling is defined as a process of feasibly synchronising the use of resources by activities to satisfy demands over time, and application problems are described in terms of this abstract domain model.

OZONE has a powerful architecture that permits a domain modeller to focus on those items that are special for a specific instance. The use of constraint managers assists in rapid identification of aspects to consider. While the work on OZONE reflects years of experience in the scheduling field, the ontology is still relatively new.

3.5 PIF

Critical in Business Process Reengineering or Enterprise Integration is the ability to share and interlink heterogeneous process models. The goal of the PIF (Process Interchange Format) project [Lee *et al.* 96] is to support the exchange of business process models across different formats and schemas. The project pursues this goal by developing PIF (a common translation language that serves as a bridge among heterogeneous process representations), translators between PIF and local process representations, and a mechanism for extending PIF to accommodate different expressive needs in a modular way (Partially Shared Views).

At the heart of PIF is a core set of classes. Some of these classes are described in the following excerpt.

In PIF, everything is an ENTITY; that is, every PIF construct is a specialization of ENTITY. There are four types of ENTITY: ACTIVITY, OBJECT, TIMEPOINT, and RELATION. These four types are derived from the definition of process in PIF: a process is a set of ACTIVITIES that stand in certain RELATIONS to one another and to OBJECTS over TIMEPOINTS [Lee *et al.* 96].

The PIF project aims to support translations such that process descriptions can be automatically translated back and forth between PIF and other process representations with as little loss of meaning as possible. If translation cannot be done fully automatically, the human efforts needed to assist the translation should be minimised. If a translator cannot translate part of a PIF process description to its target format, it should: 1) Translate as much of the description as possible (and not, for example, simply issue an error message and give up) 2) Represent any untranslatable parts so that the translator can add them back to the process description when it is translated back into PIF⁷.

⁶This builds on earlier work with OPIS [Smith 94]

⁷Most of this PIF summary was written for the PSL group by Jintae Lee, University of Hawaii, College of Business Administration

3.6 STEP-49

This representation analysis is the only one here that wasn't part of the authors' proposed set of representations. This analysis was performed by the authors at the PSL members' request as a verification check of another analysis performed for STEP-49. We include the results here as an additional contibution to the phase 2 effort.

Part 49 (Process structure and properties) [ISO 95] is an Integrated generic resource of STEP (Standard for the Exchange of Product model data) written in EXPRESS. It specifies the information necessary to specify the actions or potential actions to realize a process. This includes the relationships between the actions or potential actions in the process and the relationships between the processes that are used to realize a product. A process plan is the specification of instructions to realize a product. This part does not specify any particular process, but defines the elements to exchange process information. This part is applicable to all types of process definitions that can be represented in a discrete manner.

The constructs define the structure for specifying: relationships between processes, the effectivity of a process, the properties of a process, the resources required for the process, the properties of the resource, the representation of process, the representation of the resource, and the relationship of the process to the product. Together, these constructs can be combined to create a process plan.

Part 49 is broken up into three schemas: method_definition_schema; process_property_schema; and process_property_representation_schema. The method_definition_schema is the specification of the instructions required to perform a process that augments the product definition, defines the product, or contributes to the production of a product. The process_property_schema defines the properties of the actions of the process, the properties of the action_methods of the process, the properties of the resources to be used in the execution of the process, and the properties of the product that will result from the execution of the process. The process property_representation_schema represents the properties required by either a resource, an action, or a potential action to effect a process. This could include either a resource parameter value or an action parameter value.

Part 49 is able to cover many aspect of process representation because of the generality of the constructs. For example, there is a construct called action_method_relationship which can either be a concurrent_action_method or a serial_action_method and may be associated with a relationship_with_condition. With these constructs, one is able to model alternative tasks, concurrent tasks, parallel tasks, serial tasks, conditional tasks, iterative loops, and abstraction (decomposition). Although this representation is adequate, the level in which it is written might make it difficult for a systems developer to understand the meaning and usefulness of the constructs⁸.

3.7 TF

The O-Plan (Open Planning Architecture) Project [Currie & Tate 91, Tate *et al.* 96] is exploring issues of coordinated command, planning and control. The objective of the O-Plan Project at the Artificial Intelligence Applications Institute (AIAI) is to develop an architecture within which different agents have command (task assignment), planning and execution monitoring roles. "Task Formalism" (TF) is a language that is used to convey a detailed description of permissible actions or operations within an application area, including information about how constraints imposed on the use of these actions should be satisfied, and their effects on the domain if the actions are used.

O-Plan is a domain independent planning system. The agents in this system require the input of a domain representation in order to complete their respective tasks. Task Formalism is used to provide this detailed knowledge. Task Formalism was originally developed for the NONLIN planner in 1975 and has been extended and refined for use in O-Plan.

 $^{^8{\}rm This}$ STEP-49 summary was written for the PSL group by Craig Schlenoff, National Institute of Standards and Technology (NIST)

Task Formalism is used to give an overall hierarchical description of an application area by specifying the possible activities within the application domain and describing how those activities can be "expanded" into sets of sub-activities with a wide range of contraints imposed. Plans are generated by choosing suitable expansions for activities in the plan (i.e. refining those activities) and including the sets of more detailed sub-activities described by the chosen expansions. Ordering constraints are then satisfied to ensure that asserted effects of some actions satisfy, and continue to satisfy, conditions on the use of other actions. Other temporal and resource constraints are also included in the descriptions. These descriptions of actions form the main structure within TF, the schema. Schemas are also used in a completely uniform manner to describe tasks set to the planning system, in the same formalism. Other TF structures hold global information of various sorts and heuristic information about preferences for choices to be made during planning.

TF can be used to represent complex knowledge about a domain. This "rich" knowledge includes action effects and conditions, hierarchical relationships, temporal requirements, authority, resource needs, etc. Its constraint-based approach provides a strong, extensible approach to domain representation. When examining O-Plan's Task Formalism with respect to the requirements of NIST's Process Specification Language (PSL) it was noted that certain aspects that are more closely related to manufacturing were lacking in TF (cost data, milestones, etc.) O-Plan TF is a specific language for planning and lacks some of the generality provided by a conceptual model such as <I-N-OVA> on which it is based.

4 Results

The data of the analyses is presented in appendices A and B. Appendix A provides a cross-comparison matrix to easily see what the rankings were for each representation. Appendix B provides the detailed tables for each representation which lists the constructs identified and/or explanations which help to support a specific rating. In some cases where there were multiple contributors, such as the PIF detailed analysis ⁹, there are cited comments to show the various inputs.

Overall Candidate Coverage of PSL Core and Outer Core Requirements

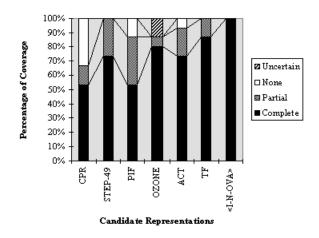

Figure 1: Overall Analysis Results

There were proportionately more outer core (41 out of 56 total, or 73%) requirements than there were

⁹The PIF analysis was compiled by a number of the PIF working group members including the authors.

core requirements (15 out of 56 total, or 23%). No effort was made to weight the importance of either the membership of the requirement to a specific set nor for its individual importance. The ratings from these tables in the appendices have been summarised in three separate figures. Figure 1 provides a chart illustrating the overall coverage for each representation. Figures 2 and 3 separate the overall results into core and outer core coverages, respectively.

In figure 1, the candidate representations are shown on the x-axis. These representations are roughly sorted by an ascending coverage rating. Each rating shows the distribution of assessments for the combined core and outer core requirements. The "complete" data set (in solid black) shows the percentage of requirements that were considered to be "completely satisfied". So, for example, OZONE and ACT were considered to "completely" satisfy around 75% of all the requirements whereas PIF and STEP-49 were around 45%. Now, if we add the set of "partially satisfied" requirements to the "completely satisfied" set we can see the summation of these percentage below the "partial" series (in grey). Given this combined set we can see, for example, that ACT and TF are around 90-95% whereas PIF is around 75%. The "none" series (in white) shows the percentage of remaining requirements that the representation was considered unable to satisfy at all. The figure also shows that a small number of uncertain entries which still remained in the OZONE analysis.

Core Candidate Coverage of PSL Requirements

Figure 2: Results of Core Analysis

Figure 2 is expressed in the same format as just described for figure 1, but figure 2 only contains the data from the core category of the requirements. Rather than resorting this group by its coverage rating as we did in figure 1, we have left the order alone. This helps to show the difference between the overall ratings vs. the core alone. We can see, for example, that while PIF had a slightly higher overall rating (in figure 1) than STEP-49, it had a lower core rating. This somewhat surprising result is discussed more in the following section.

The outer core results are reflected in figure 3. As cited above, 73% of the requirements came from this set so it is not too surprising to see that the relative distribution of the ratings is similiar to the overall rating distribution in figure 1. This data shows a definite cut-off between the ratings assigned to PIF (and the representations to the left of it) vs. OZONE (and the representations to the right of it). A result which will also be discussed in the next section is the apparently relatively low rating of CPR.

Outer Core Candidate Coverage of PSL Requirements

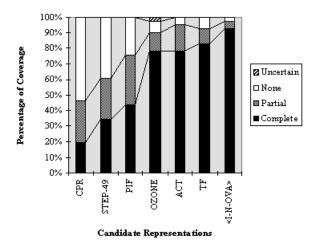

Figure 3: Results of Outer Core Analysis

5 Discussion

5.1 Analysis Issues

As we discuss these results, a few points should be made clear relating to certain issues in the analysis process. The first issue has to do with the "interpretation" of the scale provided for the analysis. This scale again was either: completely satisfy, partially satisfy, cannot satisfy, or uncertain. It is obvious that this is a very large-grained measure and is subject to a number of perspectives on what it "means" to satisfy a requirement. A more fine-grained scale could have been used but it would be even harder to explain why a representation received an 8 vs. a 7, for example.

Some members performing the analysis made the judgement that a requirement could only be met if there was a specific construct that was specifically designed to meet a given requirement. So, for example, if a representation used a frame-based syntax and did not have a slot specifically designed for "deadline management" (see requirement 2.2.4), then it did not "satisfy" the requirement. Another perspective was to look at the available constructs of a representation and to determine if there was a way in which the requirement could be expressed (e.g. deadlines can be achieved through an association of an activity status and a specific time point). The latter approach was the one taken by the authors in these analyses (with the exception of CPR, which was the result of another analyst¹⁰. This difference lead to a skewing of comparsions between analyses performed by separate analysts. Specifically, while the CPR analysis was included in this paper to associate its results with the other plan-based representations (e.g. ACT, TF), it must be understood that conclusions cannot be directly made on the comparisons between CPR and the rest presented here. The other representation analyses are considered to be homogenous.

Another issue that confuses the interpretation of these results is the repeated use of the term "core". In representations like PIF and CPR the term, core, is used to mean the set of elements that are central to the representation of a process or plan. This generally implies that the concepts which were considered to be superflous were moved outside of the core. On the other hand, when we are talking about the PSL "core" requirements, we are referring to those items that were judged by the PSL group to be "important" or

¹⁰Specifically, Adam Pease, Teknowledge, Inc.

"necessary" requirements. These requirements might map to concepts which may not be central to processes knowledge but are more reflective of PSL's perceived need. This helps to explain why the PIF-Core didn't match very well to the core requirements, but something like STEP's Part 49 did. What was core to PIF was not necessarily reflected by the PSL core requirements.

5.2 Specific Representation Results

Before we discuss some of the results of the representations reviewed here, it should be pointed out that there were 19 other representations that were reviewed as part of the phase 2 effort as well. This included representations like PERT networks, Gantt charts, KIF, Entity-Relationship diagrams, IDEF3, etc. The set in this paper was the authors' contribution¹¹ and contains most of the representations that were consistently rated very high amongst the complete phase 2 set. This rating again might be partially skewed due to possibly different perspectives on how to rank the entries.

It is not too surprising that <I-N-OVA> rated the highest in this set due to its intended use. As described in section 3.3, <I-N-OVA> is a conceptual model which can be thought of as a candidate to underly the future PSL language, just as it does with O-Plan TF. In fact it was interesting to review the few parts that <I-N-OVA> didn't address in the PSL requirements (e.g. probablistic uncertainty). O-Plan TF, SRI's ACT, and CMU's OZONE were all relatively equivalent and reflect their long pedigree in representing plan and process knowledge. It is easy to understand that we then take a step down from these more complete and polished representations to review the relatively newer, and spartan PIF-Core and CPR model (again it is possible that the CPR rating might have been higher, possibly more equivalent to PIF-Core, if viewed from another perspective). Possible future extensions to these representations could help them address some of the un-met requirements. It was interesting to note that while part 49 of STEP addressed a number of core items, its overall rating was closer to that of PIF-Core than ACT, OZONE, and O-Plan TF.

6 Conclusions

In a way, these results confirm many of the things one would expect to see when comparing these candidates against a set of rigorous process requirements. <I-N-OVA>, being the most general representation, was expected to be able to address almost all of the concepts that were part of the requirements. The notion of constraints provided an adequate representation for identfying ways to express the various PSL requirements. ACT, O-Plan TF, and OZONE representations, anchored in prototype AI planning and scheduling systems, were hypothesized to be roughly equivalent in what they could and could not handle. Since the PIF-Core and CPR model represent a much smaller and more compact set it was consistent to see a slight drop in their coverage.

The representations developed for AI planning, scheduling and in earlier process/plan interchange languages have been shown to be good "candidates" of ideas and concepts relative to the requirements defined in phase 1. It is hoped that these ideas and concepts can be used to feed into the future work on NIST's PSL project as it moves forward to phase 3 work on a proposed language.

B Detailed PSL Analysis for Each Candidate Representation

B.1 SRI's ACT Formalism Detailed PSL Analysis

Key:
 \checkmark - Completely satisfies req., * - Partially satisfies req., X - Cannot satisfy req., ? - Uncertain

	PSL Requirement	Rank	Description
1	Core Requirements		-
1.1	Representational Requirements		
1.1.1	ad hoc notes and annotations option- ally associated with any component of a plan - on-the-fly, off-the-cuff notes and documentation. This could be voice, video, as well as text. A person's ob- servation of a process might go here.	\checkmark	An individual ACT's environment con- ditions contains a comment slot where text can be inserted. This may in- clude a file reference to drawings, etc. Also, there is a property slot that holds property/value pairs that can be used- defined.
1.1.2	cost data - the cost associated with a resource or task. This could be a fixed cost, cost rate, or a cost derived from other attributes such as duration and level of effort. Costs associated with uncertainty, variability, tolerances, etc	*	ACT permits a reusable resource model that could be utilized to represent some aspects of cost.
1.1.3	level of effort - description of the amount of a resource needed, in any given unit, to accomplish a task. Some example levels of effort are equipment- hour, labor-hour, and crew size.	Х	ACT does not support a quantification of resource needs.
1.1.4	product (work item) characteristics - information about an intermediate and final product which a process will pro- duce.	*	This implementation of the ACT form- alism does not support a "produceable" model of resources that could be inter- preted as products.
1.1.5	resource - a single resource or a group of resources. Some types of resources are equipment, people, information, and in- progress goods.	\checkmark	Resources can be logically represented for use in ACTs.
1.1.6	resource requirement(s) for a task (with quantity) - the relationship between one or more resources and a task.	\checkmark	A simple association of resources and an ACT is established with the resource slot.
1.1.7	simple groups of tasks - very basic, high-level set of tasks. One example is the grouping of tasks and sequences that make up a process plan or that make up a phase.	\checkmark	An ACT's plot consists of a directed graph of nodes that represents a group- ing of actions
1.1.8	simple resource capabil- ity/characteristics - a high-level description of the characteristics of a resource. More detailed descriptions can be found in the outer core.	* RI's ACT	A rough approximation of characterist- ics of a resource can be inferred by the typed system used in ACT. (i.e. an Air- plane.1 has different characteristics than a Boat.2).

	PSL Requirement	Rank	Description
1.1.9	simple sequences - linear, time-		An ACT's plot consists of a directed
	sequential groups of tasks. More	•	graph. The nodes in this graph rep-
	sophisticated relationships such as		resent actions and the links represent a
	parallel and alternative tasks can be		partial ordering that can provide simple
	found in the outer core.		sequences.
1.1.10	simple task representation and charac-		An individual ACT's environment con-
	teristics - a simple, high-level descrip-	•	ditions contains a comment slot where
	tion of the task. More detailed rep-		text about the actions can be inserted.
	resentations can be found in the outer		Also, there is a property slot for user-
	core.		defined property/value pairing that can
			also annotate characteristics.
1.1.11	task duration - the time required to	\checkmark	Time-constraints impose any of the 13
	complete a task or group of tasks. Only		Allen relations between actions. In ad-
	simple durations are represented here.		dition to these constraints, time win-
			dows can be setup for start/end, dura-
			tion, etc.
1.1.12	task executor - who is responsible for	\checkmark	While there isn't an explicit slot
	executing a task or group of tasks. Ex-		for task executor, this property/value
	amples include a person, controller, or		could be inserted into the properties
	external company if the task is contrac-		slot.
1.0	ted out.		
1.2	Functional Requirements		The ACT meneration also and iteration
1.2.1	extensibility - there must be a mechan-	\checkmark	The ACT properties slot provides a
	ism in place to allow a user to add ad-		mechanism to allow additional user- defined information to be added to the
	ditional information to the pre-defined data constructs. One such mechanism		representation.
	could be the addition of stubs for user-		representation.
	defined information.		
1.2.2	resource allocation/deallocation for one		An ACT USE-RESOURCE statement
1.2.2	or many tasks - the assignment and re-	V	is used to provide a representation for
	lease of one or more resources to a task		resource allocation/deallocation.
	of group of tasks.		
1.2.3	simple precedence - a high-level descrip-		Various constraints can be placed on
	tion of the precedence constraints of one	v	the precedence orderings of actions.
	task on another. A more detailed de-		Temporal constraints can be used to
	scription of precedence and constraints		create specific time windows, precondi-
	can be found in the outer core.		tions can be used to express situational
			constraints that must be satisfied in or-
			der to apply the act.
2	Outer Core Requirements		
2.1	Representational Requirements		
2.1.1	abstraction - within the scope of this	\checkmark	ACTs can be arranged in a hierarchical
	project, there are three concepts of ab-		fashion that links thru the Cue gating
	straction that must be captured. (hier-		slot in a plot. In fact, an ACT is an ab-
	archy, incompleteness, ambiguity)		straction of a set of actions and those
			actions may be abstractions of other
			ACTs.
	B.1 - SF	RI's ACT	

	PSL Requirement	Rank	Description					
2.1.2	alternative task - (see complex sequences)	√	ACTs support alternative tasks in a variety of ways. A set of ACTs may share the same cue environment conditions offering alternative choices. Within a plot, conditional arcs can of-					
			fer disjuctive paths.					
2.1.3	associated illustrations and drawings	\checkmark	Property/value slots can be assigned to ACTs that contain filename pointers to graphical files, etc.					
2.1.4	complex groups of tasks - groups of tasks which have a common tie.	\checkmark	An ACT is essentially a complex group- ing of tasks (in a plot). ACTs are also connected together via Achieve, Achieve-by, etc.					
2.1.5	complex resource characteristics - a de- tailed description of the characteristics of a resource or group of resources.	*	Since ACT uses typed variables, re- sources could be grouped as instances of certain classes. Characteristics of a class could then be inferred.					
2.1.6	complex sequences - complex ordering relationships between tasks	~	ACTs (and plot nodes) can be ordered in complex relationships that support a variety of conditional, temporal possib- ilities.					
2.1.7	complex task representation and para- meters - a detailed representation of a task or group of tasks.	\checkmark	Plots provide a very detailed expression of how a task (or grouping of actions) may be completed.					
2.1.8	concurrent tasks - (see complex se- quences)	\checkmark	Concurrency is possible with parallel nodes in plots that can split/join the network.					
2.1.9	conditional tasks - a task that only needs to be performed under some pre- defined circumstance.	\checkmark	ACTs (and plot nodes) can use test metapredicates to provide conditional processes.					
2.1.10	confidence levels - a measure of cer- tainty that some attribute is true.	*	While there isn't direct support for this within ACT itself, there is a subsystem in the implementation (Gister-CL) that can reason about uncertain information about the world and actions.					
2.1.11	constraints - implicit or explicit con- straints associated with a task or re- source.	\checkmark	A variety of constraints can be placed on an ACT that can control things like applicability, temporal limits, etc.					
2.1.12	date(s) and time(s) and/or multiple duration(s) - the association of one or more dates and times and/or multiple durations with a resource or task	*	The temporal elements (windows, dur- ations, etc.) are all relative points to other temporal elements in the repres- entation.					
2.1.13	implicit/explicit resource association - an implicit or explicit dependency of a resource on another type of resource.	*	This can partially be achieved implicity. For instance, whenever we wish to say that if you use x, you must have y as well. (USE-RESOURCE $(x y)$)					
	B.1 - SRI's ACT							

	PSL Requirement	Rank	Description
2.1.14	iterative loops - a situation when a task or group of tasks repeats until a desired condition is met	\checkmark	Looping is possible by linking a plot node back to an ancestor node in the graph. Test metapredicates control the number of times.
2.1.15	manual vs. automated tasks - charac- teristics of a task can differ depending on if a human or a machine is perform- ing that task.	\checkmark	Precondition gating slots can filter which ACT is applicable.
2.1.16	manufacturing product quantity - the amount of the product that is to man- ufactured.	X	This is not part of ACT.
2.1.17	material constraints	Х	This is not supported in ACT.
2.1.18	parallel tasks	\checkmark	Parallel tasks can be defined using par- allel plot nodes.
2.1.19	parameters and variables - place hold- ers that can store a constantly changing value.	\checkmark	ACT has a typed variable system that can be bound and rebound as needed.
2.1.20	pre- and post-processing constraints	\checkmark	Preconditions and effects provide both of these.
2.1.21	queues, stacks, lists - the representation of an ordered or unordered group.	*	ACTs support lists of items.
2.1.22	resource categorization and grouping - a logical grouping of resources with a common tie.	\checkmark	Logical categorization and grouping can be done because resource can be considered to belong to a class of re- source. (e.g. airplane.1 is an airplane, etc.)
2.1.23	resource location identification of the location of a resource.	\checkmark	On pg. 23 of the cited paper, there is an example ACT that tracks resource locations.
2.1.24	resource/task combined characteristics - qualities of a resource that are depend- ent on a particular task, or qualities of a task that are dependent on a particular resource.	\checkmark	Multiple ACTs can be defined with dif- ferent gating conditions and effects that can be used to express this requirement.
2.1.25	serial tasks		Serial ordering of tasks is supported.
2.1.26	state existence constraints		The test metapredicate can be used to evaluate state existence.
2.1.27	state representations - the description of a process in terms of any combina- tion of the states of the process and/or resource.	\checkmark	State representations are central to the ACT representation.
2.1.28	temporal constraints	\checkmark	A rich set of temporal constraints can be used to cover all 13 relations.
2.1.29	uncertainty/variability/tolerance - the representation of the deviation from the nominal.	*	There are many ways that ACTs can express tolerance or variability of val- ues. (For example, you can define an earliest/latest starting time, etc.)
	B.1 - SF	RI's ACT	

	PSL Requirement	Rank	Description
2.2	Functional Requirements		-
2.2.1	ability to insert or attach a highlight (milestones) - the ability for a user to highlight a section of the process	*	This can be roughly approximated by adding property/value entries that are user-defined as milestones.
2.2.2	complex precedence - the ability to con- vey a series of tasks' ordering require- ments within a given process.	\checkmark	ACT provides a rich set of gating con- ditions.
2.2.3	convey the ancestry or class of a task - the ability to describe a task as it relates to the specialization of another, higher-level task.	\checkmark	An ACT's plot is essentially a special- ization of the overall task.
2.2.4	deadline management - the ability to consider a predetermined deadline when making decisions.	\checkmark	Time windows can express a variety of deadlines (e.g. x must happen before time1, etc.)
2.2.5	dispatching - the determination and representation of rules and guidelines to decide when items should be released for production.	\checkmark	There isn't an explicit mechanism that is designed for this purpose, but loop- ing, rebinding of variables, and a test metapredicate should be sufficient.
2.2.6	eligible resources - the ability to de- termine which resources can be chosen for a task (selection rules)	\checkmark	The same mechanism used to describe location of a resource can be used to create custom eligibility needs.
2.2.7	exception handling and recovery - the ability to specify corrective action when a task fails.	\checkmark	This is a central concern for PRS (which uses ACT). Conditional actions provide means to describe recovery procedures.
2.2.8	information exchange between tasks - the ability to represent the flow of in- formation among tasks	\checkmark	Information is exchanged via variable bindings.
2.2.9	mathematical and logical operations - the language must be able to perform mathematical and logical operations.	\checkmark	ACT supports FOL as its representa- tion system.
2.2.10	support for task/process templates - the language must allow for templates of a task or process.	\checkmark	ACTs are essentially a process tem- plates become further detailed by other ACTs.
2.2.11	support for simultaneously maintained associations of multiple levels of ab- straction - the ability to associate in- formation at multiple levels of abstrac- tion with a task.	\checkmark	Information can be associated with an ACT that is appropriate for that ACT's relative level in the process representation.
2.2.12	synchronization of multiple, parallel task sequences - the ability to specify a mechanism to coordinate two or more tasks that occur at the same time. B.1 - SE	√ RI's ACT	Parallel nodes in ACT plots' serve to synch parallel task sequences where ne- cessary.

B.2 Core Plan Representation(CPR) Detailed PSL Analysis

	PSL Requirement	Rank	Description
1	Core Requirements		
1.1	Representational Requirements		
1.1.1	ad hoc notes and annotations option-		Annotation object is contained in Pla-
	ally associated with any component of a		nObject superclass
	plan - on-the-fly, off-the-cuff notes and		
	documentation. This could be voice,		
	video, as well as text. A person's ob-		
	servation of a process might go here.		
1.1.2	cost data - the cost associated with a	Х	No comment
	resource or task. This could be a fixed		
	cost, cost rate, or a cost derived from		
	other attributes such as duration and		
	level of effort. Costs associated with		
	uncertainty, variability, tolerances, etc		
1.1.3	level of effort - description of the	\checkmark	Contained in the CPR specialization
	amount of a resource needed, in any		objects of ConsumableResource
	given unit, to accomplish a task. Some		
	example levels of effort are equipment-		
	hour, labor-hour, and crew size.		
1.1.4	product (work item) characteristics- in-	*	Work products can been given as the
	formation about an intermediate and fi-		underspecified object DomainObject.
	nal product which a process will pro-		
	duce.		
1.1.5	resource - a single resource or a group of	\checkmark	Resource object or its specializations
	resources. Some types of resources are		
	equipment, people, information, and in-		
	progress goods.		
1.1.6	resource requirement(s) for a task - the	\checkmark	Action objects (tasks) may contain Re-
	relationship between one or more re-		source objects
	sources and a task.		
1.1.7	simple groups of tasks - very basic,	\checkmark	Actions may contain sub-Actions
	high-level set of tasks. One example		
	is the grouping of tasks and sequences		
	that make up a process plan or that		
	make up a phase.		
1.1.8	simple resource capabil-	*	A suggested set of specializations
	ity/characteristics - a high-level		to Resource is provided including
	description of the characteristics of a		Consumable, Reusable, Synchronous-
	resource. More detailed descriptions		lyReusable, ExactCapacity and Non-
	can be found in the outer core.		Sharable.
	B.2 - Core Plan Re	presentat	tion (CPR)

Key:
 \checkmark - Completely satisfies req., * - Partially satisfies req., X - Cannot satisfy req., ? - Uncertain

	PSL Requirement	Rank	Description
1.1.9	simple sequences - linear, time- sequential groups of tasks. More sophisticated relationships such as parallel and alternative tasks can be found in the outer core.	\checkmark	Constraints may be assigned to Actions which enfore parallelism or serialism.
1.1.10	simple task representation and charac- teristics - a simple, high-level descrip- tion of the task. More detailed rep- resentations can be found in the outer core.	Х	No comment
1.1.11	task duration - the time required to complete a task or group of tasks. Only simple durations are represented here.	\checkmark	Actions have start and end times
1.1.12	task executor - who is responsible for executing a task or group of tasks. Ex- amples include a person, controller, or external company if the task is contrac- ted out.	\checkmark	Actions have associated Actors
1.2	Functional Requirements	37	
1.2.1	extensibility - there must be a mechan- ism in place to allow a user to add ad- ditional information to the pre-defined data constructs. One such mechanism could be the addition of stubs for user- defined information.	X	CPR is a representation only. However, any object may be extended through in- heritance.
1.2.2	resource allocation/deallocation for one or many tasks - the assignment and re- lease of one or more resources to a task of group of tasks.	Х	No comment
1.2.3	simple precedence - a high-level descrip- tion of the precedence constraints of one task on another. A more detailed de- scription of precedence and constraints can be found in the outer core.	X	CPR is only a representation. However, precedence constraints on Actions can be specified.
2	Outer Core Requirements		
2.1	Representational Requirements	,	
2.1.1	abstraction - within the scope of this project, there are three concepts of ab- straction that must be captured. (hier- archy, incompleteness, ambiguity)	\checkmark	There is no implied enforcement of com- pleteness. Uncertainty and Imprecision (fuzzy logic) constructs are included.
2.1.2	alternative task - (see complex se- quences)	*	Actions can be given aribtrary con- straints but there is no specified con- struct to describe one as an alternative to another.
2.1.3	associated illustrations and drawings	\checkmark	Arbitrary Annotations may be linked to any plan object
	B.2 - Core Plan Re	presentat	tion (CPR)

$ \begin{array}{r} 2.1.4 \\ \hline 2.1.5 \\ \hline 2.1.6 \\ \end{array} $	complex groups of tasks - groups of tasks which have a common tie. complex resource characteristics - a de- tailed description of the characteristics	X	No comment
2.1.6			
	of a resource or group of resources.	*	A hierarchy of resource types is provided
	complex sequences - complex ordering relationships between tasks	*	Arbitary types of constraints may be given to specify parallelism or serialism
2.1.7	complex task representation and para- meters - a detailed representation of a task or group of tasks.	Х	No comment
2.1.8	concurrent tasks - (see complex se- quences)	\checkmark	Actions may be constrained to run con- currently or may be unconstrained al- lowing concurrent execution if possible.
2.1.9	conditional tasks - a task that only needs to be performed under some pre- defined circumstance.	~	Actions may have constraints on exe- cution. Assumptions may also be in- cluded which trigger new Actions if the assumptions are violated.
2.1.10	confidence levels - a measure of cer- tainty that some attribute is true.	\checkmark	All low level data may be tagged with Uncertainty or Imprecision measures. High level objects like Entity or Action may be encapsulated in an Uncertain- Entity object which has an associated uncertainty or imprecision
2.1.11	constraints - implicit or explicit con- straints associated with a task or re- source.	*	Examples are given for temporal and pre- and post-condition constraints but the Constraint object is relatively un- derspecified.
2.1.12	date(s) and time(s) and/or multiple duration(s) - the association of one or more dates and times and/or multiple durations with a resource or task	*	CPR includes TemporalPoint a special- ization of which is the OMG universal time object which has both time and date. Action may be specialized to con- tain other durations but the base class only contains start and end.
2.1.13	implicit/explicit resource association - an implicit or explicit dependency of a resource on another type of resource.	*	A Resource may contain a Constraint which specified dependency on another Resource.
2.1.14	iterative loops - a situation when a task or group of tasks repeats until a desired condition is met	Х	No comment
2.1.15	manual vs. automated tasks - charac- teristics of a task can differ depending on if a human or a machine is perform- ing that task.	Х	No comment
2.1.16	manufacturing product quantity - the amount of the product that is to man- ufactured. B.2 - Core Plan Re	*	DomainObjects with associated quant- ity may be specified as products of Ac- tions.

	PSL Requirement	Rank	Description
2.1.17	material constraints	*	Constraints may state ranges about ar-
			bitrary attibutes of an Entity.
2.1.18	parallel tasks	*	Arbitary types of constraints may be
			given to specify parallelism or serialism.
2.1.19	parameters and variables - place hold-	Х	No comment
	ers that can store a constantly changing		
	value.	-1-

	quantity) - the relationship between one					
	or more resources and a task.					
1.1.7	simple groups of tasks - very basic,	\checkmark	N - include activity constraint.			
	high-level set of tasks. One example					
	is the grouping of tasks and sequences					
	that make up a process plan or that					
	make up a phase.					
1.1.8	simple resource capabil-	\checkmark	V - global \langle I-N-OVA \rangle entity/variable			
	ity/characteristics - a high-level		constraint for object to be used as a re-			
	description of the characteristics of a		source.			
	resource. More detailed descriptions					
	can be found in the outer core.					
	B.3 - <i-n-ova></i-n-ova>					

Key: $\sqrt{-}$ Completely satisfies req., * - Partially satisfies req., X - Cannot satisfy req., ? - Uncertain

	PSL Requirement	Rank	Description
1.1.9	simple sequences - linear, time- sequential groups of tasks. More sophisticated relationships such as parallel and alternative tasks can be found in the outer core.	\checkmark	O - Ordering constraint on time point associated with begin or end of any activity.
1.1.10	simple task representation and charac- teristics - a simple, high-level descrip- tion of the task. More detailed rep- resentations can be found in the outer core.	\checkmark	N - Name of activity.
1.1.11	task duration - the time required to complete a task or group of tasks. Only simple durations are represented here.	\checkmark	O - Metric temporal constraint between time points associated with begin and end of an activity.
1.1.12	task executor - who is responsible for executing a task or group of tasks. Ex- amples include a person, controller, or external company if the task is contrac- ted out.	\checkmark	A - Resource-Agent constraint. This allows for a specific "performer" of an activity.
1.2	Functional Requirements		
1.2.1	extensibility - there must be a mechan- ism in place to allow a user to add ad- ditional information to the pre-defined data constructs. One such mechanism could be the addition of stubs for user- defined information.	\checkmark	A - Open framework for adding any in- formation in the form of a constraint or annotation.
1.2.2	resource allocation/deallocation for one or many tasks - the assignment and re- lease of one or more resources to a task of group of tasks.	\checkmark	A - resource constraints should be expressive enough to support this.
1.2.3	simple precedence - a high-level descrip- tion of the precedence constraints of one task on another. A more detailed de- scription of precedence and constraints can be found in the outer core.	\checkmark	O - Ordering constraints. For example: O-Plan Task Formalism allows A —> B implying time point at end of activity A is before time point at begin of activity B. O-Plan TF also allows SEQUENCE A, B, C, to A—>B, B—>C, C —>
2	Outer Core Requirements		
2.1	Representational Requirements		
	B.3 - <i-< th=""><th>N-OVA></th><th>></th></i-<>	N-OVA>	>

	PSL Requirement	Rank	Description	
2.1.1	abstraction - within the scope of this project, there are three concepts of ab- straction that must be captured. (hier- archy, incompleteness, ambiguity)		A,N - Constraints of various types (in particular A-World State constraints) may be modelled at any abstraction level. Activity decompositons (Include activity constraints in process or activ- ity description library) (N). Missing constraints just imply a wider allowed space of behaviour. The <i-n-ova> model is specifically designed to allow for incompleteness and uncertainty in process and activity descriptions. The <i-n-ova> model is specifically de- signed to allow for incompleteness and uncertainty in process and activity de- scriptions. Specific constraints would need to have uncertainty in their for- mulation and expression <i-n-ova> makes no commitment to this.</i-n-ova></i-n-ova></i-n-ova>	
2.1.2	alternative task - (see complex se- quences)	\checkmark	disjunctive constraints may be included in the <i-n-ova> model in any place - and this is not limited to disjunctions within any one specific constraint type or sub-type. An other node can also represent conditional activities.</i-n-ova>	
2.1.3	associated illustrations and drawings	\checkmark	A - Associated information and an- notations may be states as "annotation constraints" or more generally "Miscel- laneous constraints".	
2.1.4	complex groups of tasks - groups of tasks which have a common tie.	\checkmark	N - other nodes that contain sub-plans can be used to group a task for a com- mon purpose (I.e. the detailed expres- sion of an activity).	
2.1.5	complex resource characteristics - a de- tailed description of the characteristics of a resource or group of resources.	\checkmark	A - Resource constraints or Agent con- straints can describe these characterist- ics.	
2.1.6	complex sequences - complex ordering relationships between tasks	\checkmark	O - ordering constraints can describe a variety of necessary relationships.	
2.1.7	complex task representation and para- meters - a detailed representation of a task or group of tasks.	\checkmark	N - Nodes that include activities can take into account concepts such as ap- plicability, performance limits, resource usage, number of constraints on its con- ditions, suitable parameter bindings, etc.	
2.1.8	concurrent tasks - (see complex sequences)		O - activities can be constrained to have "concurrent" execution.	
B.3 - <i-n-ova></i-n-ova>				

	PSL Requirement	Rank	Description		
2.1.9	conditional tasks - a task that only needs to be performed under some pre-	\checkmark	N - other nodes may also represent a conditional "if then else" within the		
0.1.10	defined circumstance.	v	plan.		
2.1.10	confidence levels - a measure of cer- tainty that some attribute is true.	X	<i-n-ova> does not contain a mech- anism for probablilistic certainty.</i-n-ova>		
2.1.11	constraints - implicit or explicit con- straints associated with a task or re- source.	\checkmark	<i-n-ova> views a plan as a set of constraints.</i-n-ova>		
2.1.12	date(s) and time(s) and/or multiple duration(s) - the association of one or more dates and times and/or multiple durations with a resource or task	\checkmark	O - metric temporal constraints can re- late a given time point to an actual time or calendar reference.		
2.1.13	implicit/explicit resource association - an implicit or explicit dependency of a resource on another type of resource.	\checkmark	A,N - Resource constraints can expli- citly be attached to an activity. A node that contains sub-plans implicity con- strains resource usage though its sub- constraints.		
2.1.14	iterative loops - a situation when a task or group of tasks repeats until a desired condition is met	\checkmark	N - other nodes can represent an encap- sulation of iteration or for-each.		
2.1.15	manual vs. automated tasks - charac- teristics of a task can differ depending on if a human or a machine is perform- ing that task.	\checkmark	A - Misc contraints can be created to characterize specialized attribute re- quirements.		
2.1.16	manufacturing product quantity - the amount of the product that is to man- ufactured.	\checkmark	A - Resource constraints can be used to control the maximum allowable amount of the resource.		
2.1.17	material constraints	\checkmark	A - resource constraints can be used to describe specialized characteristics. "always" constraints can be used to de- clare unchanging global information.		
2.1.18	parallel tasks	\checkmark	O - ordering constraints can describe activities that occur in parallel.		
2.1.19	parameters and variables - place hold- ers that can store a constantly changing value.	\checkmark	V - entity/variable constraints can be used to manage "place holders" that can take on a range of values.		
2.1.20	pre- and post-processing constraints	\checkmark	O - input and output temporal con- straints are used to describe what should hold immediately before or after a given timepoint.		
2.1.21	queues, stacks, lists - the representation of an ordered or unordered group.	*	<i-n-ova> does not have an explicit representation for data structures such as queues or stacks.</i-n-ova>		
2.1.22	resource categorization and grouping - a logical grouping of resources with a common tie.	\checkmark	It is anticipated that a representa- tion language that expresses the <i-n- OVA> model will use a sorted first or- der logic.</i-n- 		
	B.3 - <i-n-ova></i-n-ova>				

	PSL Requirement	Rank	Description		
2.1.23	resource location identification of the location of a resource.	V	A, V - A-Resource constraints can add information such as location, en- tity/variables can be used to update a location attribute.		
2.1.24	resource/task combined characteristics - qualities of a resource that are depend- ent on a particular task, or qualities of a task that are dependent on a particular resource.	\checkmark	O,N - This requirement can be met by creating alternate "include activity" nodes that utilize the same resources, but may have different input temporal constraints.		
2.1.25	serial tasks	\checkmark	O - ordering constraints are used to de- clare activites in serial.		
2.1.26	state existence constraints	\checkmark	O - input temporal constraints specify those things that are required to hold before a given timepoint (which may be attached to an activity).		
2.1.27	state representations - the description of a process in terms of any combina- tion of the states of the process and/or resource.	\checkmark	A - World State constraints act on the plan state representation.		
2.1.28	temporal constraints	\checkmark	O - Temporal modelling is performed by using timepoints and ordering con- straints.		
2.1.29	uncertainty/variability/tolerance - the representation of the deviation from the nominal.	\checkmark	The <i-n-ova> model is specifically designed to allow for incompleteness and uncertainty in process and activity descriptions. Specific constraints would need to have uncertainty in their for- mulation and expression <i-n-ova> makes no commitment to this.</i-n-ova></i-n-ova>		
2.2	Functional Requirements				
2.2.1	ability to insert or attach a highlight (milestones) - the ability for a user to highlight a section of the process	*	A - Misc or Annotation constraints can be attached to nodes to give them "milestone significance".		
2.2.2	complex precedence - the ability to con- vey a series of tasks' ordering require- ments within a given process.	√ 	O - Ordering constraints can be gener- ally specified to establish node preced- ence.		
2.2.3	convey the ancestry or class of a task - the ability to describe a task as it relates to the specialization of another, higher-level task.	\checkmark	N - other node constraints can be used to encapsulate specialized sub-plans.		
2.2.4	deadline management - the ability to consider a predetermined deadline when making decisions.	\checkmark	O - Ordering constraints are used to arrange activities within specified tem- poral constraints.		
2.2.5	dispatching - the determination and representation of rules and guidelines to decide when items should be released for production.	\checkmark	O - Input temporal constaints can be placed on activities that release repres- ent releasing items for production.		
	B.3 - <i-n-ova></i-n-ova>				

	PSL Requirement	Rank	Description
2.2.6	eligible resources - the ability to de- termine which resources can be chosen for a task (selection rules)	\checkmark	A - Resource constraints for an activ- ity describe a sorted requirement for re- source usage.
2.2.7	exception handling and recovery - the ability to specify corrective action when a task fails.	\checkmark	O - input and output temporal constraints can be used to specify what should hold before and after a timepoint (therefore an activity).
2.2.8	information exchange between tasks - the ability to represent the flow of in- formation among tasks	\checkmark	V - Information is shared between nodes thru entity/variable constraints.
2.2.9	mathematical and logical operations - the language must be able to perform mathematical and logical operations.	\checkmark	The expressions in <i-n-ova> are considered to be based in first order lo- gic that will allow for logical and math- ematical manipulation.</i-n-ova>
2.2.10	support for task/process templates - the language must allow for templates of a task or process.	\checkmark	N - other nodes and include activity nodes are linked in a "generic process template" that is applicable for use as- suming the constraints are satisfied.
2.2.11	support for simultaneously maintained associations of multiple levels of ab- straction - the ability to associate in- formation at multiple levels of abstrac- tion with a task.	\checkmark	A - Constraints can be attached at any level of a node hierarchy that would be appropriate for that model.
2.2.12	synchronization of multiple, parallel task sequences - the ability to specify a mechanism to coordinate two or more tasks that occur at the same time. B.3 - < I-	V N-OVA >	O - Temporal constraints can be at- tached to activities that make the hard requirement that begin/end timepoints are equal.

B.4 OZONE Scheduling Ontology Detailed PSL Analysis

	PSL Requirement	Rank	Description	
1	Core Requirements		-	
1.1	Representational Requirements			
1.1.1	ad hoc notes and annotations option- ally associated with any component of a plan - on-the-fly, off-the-cuff notes and	?	Need more information.	
	documentation. This could be voice, video, as well as text. A person's ob- servation of a process might go here.			
1.1.2	cost data - the cost associated with a resource or task. This could be a fixed cost, cost rate, or a cost derived from other attributes such as duration and level of effort. Costs associated with uncertainty, variability, tolerances, etc	*	There is no explicit cost property for re- sources or tasks in OZONE, but some aspects of cost can be treated as a prop- erty that is a function of the domain (i.e. the same was as LAND or SPEED are noted in the paper).	
1.1.3	level of effort - description of the amount of a resource needed, in any given unit, to accomplish a task. Some example levels of effort are equipment- hour, labor-hour, and crew size.	V	Demands can be defined that explicitly represent the quantity required. Activ- ity RESOURCE-REQUIREMENTS impose resource usage/comsumption constraints for the activity to execute.	
1.1.4	product (work item) characteristics- in- formation about an intermediate and fi- nal product which a process will pro- duce.	\checkmark	OZONE uses a distinct concept defin- ition for a product. Intermediate product information and work item characteristics can be attached directly to a product.	
1.1.5	resource - a single resource or a group of resources. Some types of resources are equipment, people, information, and in- progress goods.	\checkmark	A resource is a distinct concept defin- ition in OZONE. A variety of resource types are supported.	
1.1.6	resource requirement(s) for a task - the relationship between one or more re- sources and a task.	\checkmark	An activity can be defined with rela- tionships to resources that it requires.	
1.1.7	simple groups of tasks - very basic, high-level set of tasks. One example is the grouping of tasks and sequences that make up a process plan or that make up a phase.	\checkmark	OZONE supports the grouping of tasks in a variety of ways. Tasks (activities) can be grouped into those that fulfill a demand, produce a product, or are involved in a hierarchical ordering.	
1.1.8	simple resource capabil- ity/characteristics - a high-level description of the characteristics of a resource. More detailed descriptions can be found in the outer core.	V	A variety of capabilites/characteristics can be assigned to a resource via prop- erties. (e.g. capacity, amount of set-up time needed, etc.)	
B.4 - OZONE Scheduling Ontology				

Key: $\sqrt{-}$ Completely satisfies req., * - Partially satisfies req., X - Cannot satisfy req., ? - Uncertain

	PSL Requirement	Rank	Description
1.1.9	simple sequences - linear, time- sequential groups of tasks. More sophisticated relationships such as parallel and alternative tasks can be found in the outer core.	\checkmark	OZONE contains INTERVAL- RELATIONS that can easily handle simple linear sequencing.
1.1.10	simple task representation and charac- teristics - a simple, high-level descrip- tion of the task. More detailed rep- resentations can be found in the outer core.	?	Need more information.
1.1.11	task duration - the time required to complete a task or group of tasks. Only simple durations are represented here.	\checkmark	OZONE activities contain a "duration" property for this purpose.
1.1.12	task executor - who is responsible for executing a task or group of tasks. Ex- amples include a person, controller, or external company if the task is contrac- ted out.	\checkmark	A task executor can be modelled as a required resource for the activity.
1.2	Functional Requirements		
1.2.1	extensibility - there must be a mechan- ism in place to allow a user to add ad- ditional information to the pre-defined data constructs. One such mechanism could be the addition of stubs for user- defined information.	√ 	OZONE puts forward a concept of model specialization. Elements can be added that specialize the representation for a target domain.
1.2.2	resource allocation/deallocation for one or many tasks - the assignment and re- lease of one or more resources to a task of group of tasks.	\checkmark	Resources provide Allocate-Capacity and Deallocate-Capacity capabilities and Activities provide reserve-resources and free-resources capabilities.
1.2.3	simple precedence - a high-level descrip- tion of the precedence constraints of one task on another. A more detailed de- scription of precedence and constraints can be found in the outer core.	\checkmark	Various constraints can be defined to regulate precedence relationships of activities.
2	Outer Core Requirements		
2.1 2.1.1	Representational Requirements abstraction - within the scope of this project, there are three concepts of ab- straction that must be captured. (hier- archy, incompleteness, ambiguity)	*	To a degree, it can be stated that a constraint-based approach permits a model to be incomplete and vague on everything, except those items that are necessary to meet requirements. (e.g. Schedule these tasks in any order you like, but just make sure C is after B,
	B.4 - OZONE Sch	neduling	etc.) What is described in the require- ment though is more of a runtime test condition. Ontology

	PSL Requirement	Rank	Description
2.1.2	alternative task - (see complex se-	\checkmark	Two activities can be defined that have
	quences)		the same effects. The scheduler can
			then select an alternative that satisfies
			the requirement.
2.1.3	associated illustrations and drawings	?	Need more information.
2.1.4	complex groups of tasks - groups of	\checkmark	OZONE supports complex grouping of
	tasks which have a common tie.		tasks. For example, a set of tasks can
			be grouped that meet the requirements
			for a specific demand, a set of tasks that
			produce a work item can be attached to
			the specific product as well.
2.1.5	complex resource characteristics - a de-	\checkmark	OZONE provides a variety of ways
	tailed description of the characteristics		to assign characteristics to resources.
	of a resource or group of resources.		For example: associating state informa-
			tion with a resource, physical properties
0.1.0	1 1 1	,	(range, speed), capacity models, etc.
2.1.6	complex sequences - complex ordering	\checkmark	Complex ordering relationships can be
	relationships between tasks		defined via INTERVAL-RELATIONS.
			(e.g. BEFORE, SAME-END, CON-
2.1.7	complex tools representation and none	/	TAINS, etc.) An activity can be defined with a com-
2.1.1	complex task representation and para- meters - a detailed representation of a	\checkmark	plex set of properties. OZONE activit-
	task or group of tasks.		ies support an explicit set of pararmet-
	task of group of tasks.		ers that can influence the representa-
			tion of the task.
2.1.8	concurrent tasks - (see complex se-		An activity can contain temporal rela-
2.1.0	quences)	V	tionships to other activities. If a rela-
			tionship of same-start and same-end is
			defined then the two activities are con-
			strained to be concurrent.
2.1.9	conditional tasks - a task that only	*	At a high level, we can say that an
	needs to be performed under some pre-		activity is conditional because its exe-
	defined circumstance.		cution is dependent on outstanding de-
			mands. However, there does not seem
			to be an explicit conditional structure.
2.1.10	confidence levels - a measure of cer-	Х	No support for a measure of certainty.
	tainty that some attribute is true.		
2.1.11	constraints - implicit or explicit con-	\checkmark	OZONE presumes an underlying
	straints associated with a task or re-		constraint-based solution framework.
	source.		
	B.4 - OZONE Scl	neduling	Ontology

	PSL Requirement	Rank	Description		
2.1.12	date(s) and time(s) and/or multiple duration(s) - the association of one or more dates and times and/or multiple durations with a resource or task	*	OZONE uses various date/time re- lationships and assumes the exist- ence of TIME-POINTS, and TIME- INTERVALS. While there is support for multiple durations (e.g. duration of an activity, duration of setup-time for a resource, etc.), a specific requirement of multiple durations for the overall activ- ity does not seem possible.		
2.1.13	implicit/explicit resource association - an implicit or explicit dependency of a resource on another type of resource.	\checkmark	Various levels of implicit/explicit re- source associations can be made (i.e. sub-resources for aggregation, dynamic compatibility between 2 resource as- signments, etc.)		
2.1.14	iterative loops - a situation when a task or group of tasks repeats until a desired condition is met	Х	OZONE does not appear to support it- eration or looping constructs.		
2.1.15	manual vs. automated tasks - charac- teristics of a task can differ depending on if a human or a machine is perform- ing that task.	\checkmark	OZONE does not make an explicit dis- tininction of this type, but it would seem possible to create two activit- ies, one that represented the manual task and one that represented the auto- matic task and any "differing" would be defined by each respective activity.		
2.1.16	manufacturing product quantity - the amount of the product that is to man- ufactured.	\checkmark	An explicit slot for specifying product quantity is part of a demand in OZONE.		
2.1.17	material constraints	\checkmark	OZONE has an explicit slot for material constraints as part of a demand (i.e. the type of material to be used).		
2.1.18	parallel tasks	\checkmark	Nodes in OZONE's networks of activit- ies can be ordered in parallel.		
2.1.19	parameters and variables - place hold- ers that can store a constantly changing value.	\checkmark	The OZONE ontology has parameters (e.g. an activity accepts a quantity from demand) and variables (e.g. re- cording changes in state).		
2.1.20	pre- and post-processing constraints	\checkmark	A variety of pre and post processing constraints apply to activities. (e.g. (pre) state existence (post) duration be- fore next activity, etc.)		
2.1.21	queues, stacks, lists - the representation of an ordered or unordered group.	*	Lists of elements only.		
2.1.22	resource categorization and grouping - a logical grouping of resources with a common tie.	V	OZONE supports a rich set of categor- ies and groupings of resources based on their usages, atomicity, capacity, etc.		
L	B.4 - OZONE Scheduling Ontology				

2.1.23	resource location identification of the	1	OZONE has an applicit also in a da
$2\ 1\ 24$	location of a resource.	v	OZONE has an explicit slot in a de- mand for the ORIGIN and DESTINA- TION for a material.
2,1,2,1	resource/task combined characteristics - qualities of a resource that are depend- ent on a particular task, or qualities of a task that are dependent on a particular resource.	\checkmark	Combined activity/resource character- istics are utilized in evaluating static and dynamic compatibility constraints.
2.1.25	serial tasks	\checkmark	Simple serial assignment falls under a "before" interval.
2.1.26	state existence constraints	\checkmark	Activities and resources can be in a given state and requirements about state existence can be applied.
2.1.27	state representations - the description of a process in terms of any combina- tion of the states of the process and/or resource.	\checkmark	Activities and resources can be repres- ented as being in certain states.
2.1.28	temporal constraints	\checkmark	A variety of constraints: absolute- time-constraint, relative-time- constraint (interval-relations, duration- constraints)
2.1.29	uncertainty/variability/tolerance - the representation of the deviation from the nominal.	*	Various upper/lower bounded values support variability and tolerance of as- signment values, but probabilistic un- certainty is not supported.
2.2	Functional Requirements		
2.2.1	ability to insert or attach a highlight (milestones) - the ability for a user to highlight a section of the process	X	No support for this.
2.2.2	complex precedence - the ability to con- vey a series of tasks' ordering require- ments within a given process.	\checkmark	Duration-Constraints, interval- relations, state requirements, and aspects of demand management all combine to provide complex precedence mechanisms.
2.2.3	convey the ancestry or class of a task - the ability to describe a task as it relates to the specialization of another, higher-level task.	\checkmark	Class ancestry in OZONE is expressed thru its extension mechanism of model specialization.
2.2.4	deadline management - the ability to consider a predetermined deadline when making decisions.	\checkmark	Deadline management is possible via RELEASE-DATE, DUE-DATE prop- erties of a demand.
2.2.5	dispatching - the determination and representation of rules and guidelines to decide when items should be released for production. B.4 - OZONE Scl	\checkmark	Dispatching is encompassed in the demand-product combined capabilities. Work item generation is linked to explicit elements of demand.

	PSL Requirement	Rank	Description
2.2.6	eligible resources - the ability to de- termine which resources can be chosen for a task (selection rules)	\checkmark	OZONE maintains the "eligibility" of resources and also provides other USAGE-RESTRICTIONS that can allow a richer model of restrictions (e.g. UNAVAILABILITY-INTERVALS re- flect time periods where a resource is not eligible, etc.)
2.2.7	exception handling and recovery - the ability to specify corrective action when a task fails.	Х	No support for this.
2.2.8	information exchange between tasks - the ability to represent the flow of in- formation among tasks	\checkmark	OZONE supports paramaters passing to exchange information between vari- ous elements (e.g. demand information is passed to an activity, etc.)
2.2.9	mathematical and logical operations - the language must be able to perform mathematical and logical operations.	\checkmark	Constraint expressions use mathemat- ical and logical constructs in OZONE.
2.2.10	support for task/process templates - the language must allow for templates of a task or process.	\checkmark	The ontological element "activity" is a template for what a task should be. The various properties are expected to be filled in and new slots can be added to extend this base concept.
2.2.11	support for simultaneously maintained associations of multiple levels of ab- straction - the ability to associate in- formation at multiple levels of abstrac- tion with a task.	\checkmark	Constraints can be added at any level of abstraction to further define the re- quirements on the target space. In the example listed, you would require 5 people (resources). Next you may add a constraint on those resources (special ability). Next you may add a very spe- cific contraint (who they are), etc.
2.2.12	synchronization of multiple, parallel task sequences - the ability to specify a mechanism to coordinate two or more tasks that occur at the same time.	\checkmark	Multiple activities can be synchron- ized when parallel via INTERVAL- RELATIONS.
	B.4 - OZONE Scl	neduling	Ontology

B.5 PIF (v.1.1) Detailed PSL Analysis

	PSL Requirement	Rank	Description
1	Core Requirements		
1.1	Representational Requirements		
1.1.1	ad hoc notes and annotations option- ally associated with any component of a plan - on-the-fly, off-the-cuff notes and documentation. This could be voice, video, as well as text. A person's ob- servation of a process might go here.	*	This requirement is partially filled through the use of the "documentation" slot and the "user-attributes" that can be attached to PIF entities.
1.1.2	cost data - the cost associated with a resource or task. This could be a fixed cost, cost rate, or a cost derived from other attributes such as duration and level of effort. Costs associated with uncertainty, variability, tolerances, etc.	X	PIF does not address resource or task cost.
1.1.3	level of effort - description of the amount of a resource needed, in any given unit, to accomplish a task. Some example levels of effort are equipment- hour, labor-hour, and crew size.	Х	PIF can say that an activity uses some object, but does not have a mechanism to quantify the usage.
1.1.4	product (work item) characteristics- in- formation about an intermediate and fi- nal product which a process will pro- duce.	*	While PIF can represent objects that are created, modified, or used during an activity, there is no provision for at- taching characteristics to that object. 2-Dec-96, As per Lee: should be * (par- tial) because the PIF-CORE provides a means of specifying such characteristics via User-Attributes and PSV's.
1.1.5	resource - a single resource or a group of resources. Some types of resources are equipment, people, information, and in- progress goods.	\checkmark	Activities can specify which objects (re- sources) were created, modified or used
1.1.6	resource requirement(s) for a task (with quantity) - the relationship between one or more resources and a task.	*	PIF cannot represent quantity of an object (resource).
1.1.7	simple groups of tasks - very basic, high-level set of tasks. One example is the grouping of tasks and sequences that make up a process plan or that make up a phase. B.5 - PI	√ F (v1.1)	PIF can express grouping of activit- ies through decompositional relation- ships. 2-Dec-96, Gruninger: satisfied if the grouping is a deterministic activity, but is not satisfied in general for non- deterministic activities

Key: $\sqrt{-}$ Completely satisfies req., * - Partially satisfies req., X - Cannot satisfy req., ? - Uncertain

PSL Requirement Ranl 1.1.8 simple resource capability or character- istics - a high-level description of the characteristics of a resource. More de- tailed descriptions can be found in the outer core. * 1.1.9 simple sequences - linear, time- sequential groups of tasks. More sophisticated relationships such as parallel and alternative tasks can be found in the outer core. ✓ 1.1.10 simple task representation and charac- teristics - a simple, high-level descrip- tion of the task. More detailed rep- resentations can be found in the outer core. ✓ 1.1.11 task duration - the time required to complete a task or group of tasks. Only simple durations are represented here. ✓ 1.1.12 task executor - who is responsible for executing a task or group of tasks. Ex- amples include a person, controller, or external company if the task is contrac- ted out. ✓ 1.2 Functional Requirements ✓	Description
sequential groups of tasks. More sophisticated relationships such as parallel and alternative tasks can be found in the outer core. Image: Sequencial groups of tasks can be found in the outer core. 1.1.10 simple task representation and characteristics - a simple, high-level description of the task. More detailed representations can be found in the outer core. 1.1.11 task duration - the time required to complete a task or group of tasks. Only simple durations are represented here. 1.1.12 task executor - who is responsible for executing a task or group of tasks. Examples include a person, controller, or external company if the task is contracted out. 1.2 Functional Requirements	16-Nov-96, X to * as per Tate's in- put: PIF Core does not have an explicit mechanism to describe the "capability" of an object (when used in the role of re- source) but it does allow for attributes of such objects to be stated. Capability limited to agents.
teristics - a simple, high-level description of the task. More detailed representations can be found in the outer core. 1.1.11 task duration - the time required to complete a task or group of tasks. Only simple durations are represented here. 1.1.12 task executor - who is responsible for executing a task or group of tasks. Examples include a person, controller, or external company if the task is contracted out. 1.2 Functional Requirements	The use of timepoints and temporal relationships will provide simple se- quences. 2-Dec-96, Gruninger: This re- quirement is satisfied insofar as we can write the definition of an activity for simple and complex sequences. How- ever, we cannot express the definition of simple and complex sequences using PIF-Core.
complete a task or group of tasks. Only simple durations are represented here. 1.1.12 task executor - who is responsible for executing a task or group of tasks. Examples include a person, controller, or external company if the task is contracted out. 1.2 Functional Requirements	PIF can represent a task with its effects, conditions, etc. Also, textual high-level descriptions can be attached via the documentation attribute.
executing a task or group of tasks. Examples include a person, controller, or external company if the task is contracted out. 1.2 Functional Requirements	16-Nov-96, Change from $$ to * as per Tate's input: An activity can contain begin and end points, but PIF Core itself does not support quantities for duration. 4-Dec-96, Changed back to per Gruninger and Lee: This can be captured, since the axiomatization of time points in the situation calculus means that time points are isomorphic to the real numbers.
	PIF can describe a "performs" relation- ship between activities and agents.
ism in place to allow a user to add ad- ditional information to the pre-defined data constructs. One such mechanism could be the addition of stubs for user- defined information. B.5 - PIF (v1.1	PIF has a "user-attributes" slot defined at the highest level of the hierarchy that can store user-defined information.

	PSL Requirement	Rank	Description
1.2.2	resource allocation/deallocation for one or many tasks - the assignment and re- lease of one or more resources to a task of group of tasks.	*	16-Nov-96, Change from * to $$ as per Tate's input that pointed out that spe- cifying individual resource units are not part of the requirement. PIF can rep- resent objects that are created, modi- fied, or used during an activity. 4-Dec- 96, Changed back to * as per Gruninger and Lee. The feeling is that resource exclusivity etc. is not explicit.
1.2.3	simple precedence - a high-level descrip- tion of the precedence constraints of one task on another. A more detailed de- scription of precedence and constraints can be found in the outer core.	\checkmark	PIF can provide a detailed descrip- tion of activities' relationships to other activities. Temporal, causal, and de- compositional relationships can be used to impose constraints on the preced- ence.
2	Outer Core Requirements		
2.1 2.1.1	Representational Requirements abstraction - within the scope of this project, there are three concepts of ab- straction that must be captured.	√	PIF supports decompositional relation- ships between activities. Therefore activities can be arranged in an ab- stract, incomplete, or ambiguous fash- ion.
2.1.2	alternative task - (see complex se- quences)	\checkmark	PIF's use of decisions allows for a se- lection of alternative tasks. 4-Dec-96 Gruninger: Although decisions can be used to select an activity based on state, this cannot be used to define arbitrary nondeterministic choices e.g. do A or do B.
2.1.3	associated illustrations and drawings	*	16-Nov-96, Change from X to * as per Tate's input: "[a PIF user] can use the documentation or user attribute slots for this."
2.1.4	complex groups of tasks - groups of tasks which have a common tie.	*	This requirement asks for information that goes beyond specifying which sub- activities occur in a group and asks whether there is explicit representa- tion about the overall group (total cost, total resources used in decomposition, etc.) 2-Dec-96, Gruninger: satisfied if the grouping is a deterministic activity, but is not satisfied in general for non- deterministic activities
2.1.5	complex resource characteristics - a de- tailed description of the characteristics of a resource or group of resources.	Х	See 1.1.8.
	B.5 - PI	F(v1.1)	

	PSL Requirement	Rank	Description
2.1.6	complex sequences - complex ordering relationships between tasks complex task representation and para-	*	PIF can handle concepts such as: al- ternative, parallel, serial, concurrent activities. Timepoints and temporal re- lationships provide these requirements. 2-Dec-96, Gruninger: This requirement is satisfied insofar as we can write the definition of an activity for simple and complex sequences. However, we can- not express the definition of simple and complex sequences using PIF-Core. PIF's highly expressive pif-sentences
910	meters - a detailed representation of a task or group of tasks.	,	can be used to give a detailed represent- ation of what an activity needs and does (hierarchical activities are considered "grouped"). More specialized charac. (e.g. uniterruptability) cannot be ex- pressed. See 2.1.6.
2.1.8	concurrent tasks - (see complex se- quences)	\checkmark	
2.1.9	conditional tasks - a task that only needs to be performed under some pre- defined circumstance.	\checkmark	PIF uses the entity, decision, to represent a conditional activity.
2.1.10	confidence levels - a measure of cer- tainty that some attribute is true.	Х	PIF sentences are boolean.
2.1.11	constraints - implicit or explicit con- straints associated with a task or re- source.	\checkmark	Activities and objects (resources) in- herit constraint slots for such purposes.
2.1.12	date(s) and time(s) and/or multiple duration(s) - the association of one or more dates and times and/or multiple durations with a resource or task	*	Activities can express durations through relative begin and end timepoints.
2.1.13	implicit/explicit resource association - an implicit or explicit dependency of a resource on another type of resource.	V	PIF representation of object (resource) component can be interpreted to some extent as a dependency. (e.g. Object A has components Object B and C. Therefore using Object A implies using Object B and C as well.) 2-Dec-96, * to $$, Lee: Represent [a] dependency via Precondition and Postcondition of an activity. A resource X requires an- other resource Y if the Use activity that uses X has as a precondition the avail- ability of the resource Y
2.1.14	iterative loops - a situation when a task or group of tasks repeats until a desired condition is met	\checkmark	This can be satisfied using decisions or preconditions and postconditions of activities.
	B.5 - PI	$\overline{F(v1.1)}$	

	PSL Requirement	Rank	Description
2.1.15	manual vs. automated tasks - charac- teristics of a task can differ depending on if a human or a machine is perform- ing that task.	Х	No information is explicitly captured for this in the PIF-CORE.
2.1.16	manufacturing product quantity - the amount of the product that is to man- ufactured.	X	Not in PIF-CORE, sounds like a PSV.
2.1.17	material constraints	X	PIF contains no support for material constraints.
2.1.18	parallel tasks	\checkmark	See 2.1.6. 4-Dec-96 Gruninger: This re- quirement is satisfied insofar as we can write the definition of an activity for parallel or serial tasks. However, we cannot express the definition of paral- lel or serial tasks using PIF-Core.
2.1.19	parameters and variables - place hold- ers that can store a constantly changing value.	\checkmark	PIF activities utilize variables in pif- sentences.
2.1.20	pre- and post-processing constraints	\checkmark	PIF declares what must be true before an activity is performed and also as- serts what must be true after the activ- ity completes.
2.1.21	queues, stacks, lists - the representation of an ordered or unordered group.	*	PIF provides a list structure.
2.1.22	resource categorization and grouping - a logical grouping of resources with a common tie.	*	To some extent, PIF can address this by explicitly listing which objects (resources) each activity uses/creates/modifies. PIF can also describe which objects are components of other objects, but logical grouping (outside of activity) seems to be absent.
2.1.23	resource location identification of the location of a resource.	X	There is no facility in the PIF-CORE to address this relationship.
2.1.24	resource/task combined characteristics - qualities of a resource that are depend- ent on a particular task, or qualities of a task that are dependent on a particular resource.	X	There is no facility in the PIF-CORE to address this relationship.
2.1.25	serial tasks	√ (v1.1)	PIF can order activities in serial. 4- Dec-96 Gruninger: This requirement is satisfied insofar as we can write the definition of an activity for parallel or serial tasks. However, we cannot ex- press the definition of parallel or serial tasks using PIF-Core.
	D.0 - P1	л (VI.I)	

	PSL Requirement	Rank	Description
2.1.26	state existence constraints	\checkmark	PIF can constrain when activities can be executed using activity precondi- tions.
2.1.27	state representations - the description of a process in terms of any combina- tion of the states of the process and/or resource.	*	PIF can describe state changes for activities but not for objects (re- sources).
2.1.28	temporal constraints	*	PIF can relate activities through shared begin/end points, but a PSV is required to appropriately address temporal rela- tionships (other than "before"). 2-Dec- 96, X to *, Lee: BEFORE is available and some temporal constraints can be expressed using the begin and end timepoints.
2.1.29	uncertainty/variability/tolerance - the representation of the deviation from the nominal. Functional Requirements	X	PIF does not have a facility for man- aging uncertainty.
2.2.1	ability to insert or attach a highlight (milestones) - the ability for a user to highlight a section of the process	Х	Not in PIF-CORE
2.2.2	complex precedence - the ability to con- vey a series of tasks' ordering require- ments within a given process.	\checkmark	The use of preconditions and decisions allows for complex, conditional activity orderings. 2-Dec-96, Gruninger: This requirement is satisfied insofar as we can write the definition of an activ- ity for simple and complex sequences. However, we cannot express the defin- ition of simple and complex sequences using PIF-Core.
2.2.3	convey the ancestry or class of a task - the ability to describe a task as it relates to the specialization of another, higher-level task.	\checkmark	PIF's decompositional relationships define a hierarchy of specialization.
2.2.4	deadline management - the ability to consider a predetermined deadline when making decisions.	*	PIF's activities utilize an activity- status relation which is linked to timepoints. Therefore PIF can set timepoints for when an activity must be at a certain status.
2.2.5	dispatching - the determination and representation of rules and guidelines to decide when items should be released for production.	X	This level of object detail is not expli- citly represented in PIF.
	B.5 - PI	F(v1.1)	

 2.2.6 eligible resources - the ability to determine which resources can be chosen for a task (selection rules) 2.2.7 exception handling and recovery - the ability to specify corrective action when a task fails. 	*	 In terms of agents (as resources) PIF can explicitly describe their capability, thus making them eligible. PIF does not provide the "eligibility" of other non-agent objects. 6-Nov-96 as per Yan Jin's input: PIF's conditional activities can respond to exception handling and recovery. 4-Dec-96 Gruninger: Depends on interpretation. PIF cannot (a) while the (b) is simply a decision activity. (see below) There are two interpretations of this construct: a) global occurrence constraint which must be satisfied regardless of what activities are occurring at
ability to specify corrective action when	V	conditional activities can respond to ex- ception handling and recovery. 4-Dec- 96 Gruninger: Depends on interpreta- tion. PIF cannot (a) while the (b) is simply a decision activity. (see below) There are two interpretations of this construct: a) global occurrence con- straint which must be satisfied regard- less of what activities are occurring at
		any point in time.b) a conditional activ- ity which occurs at specific points dur- ing a complex activity.
2.2.8 information exchange between tasks - the ability to represent the flow of in- formation among tasks	*	The flow can be partially mapped out by illustrating which activities cre- ate/modify/use objects.
2.2.9 mathematical and logical operations - the language must be able to perform mathematical and logical operations.	\checkmark	PIF has a mechanism to derive boolean results for conditionals, etc.
2.2.10 support for task/process templates - the language must allow for templates of a task or process.	*	PIF does not provide this explicit form of meta element, but PIF design ele- ments can be reused.
2.2.11 support for simultaneously maintained associations of multiple levels of ab- straction - the ability to associate in- formation at multiple levels of abstrac- tion with a task.	\checkmark	PIF decomposition allows a designer to attach/modify activity relationships at any level of abstraction.
2.2.12 synchronization of multiple, parallel task sequences - the ability to specify a mechanism to coordinate two or more tasks that occur at the same time.	* IF (v1.1)	PIF does not contain any real-time event signalling and notification that could manage multiple, parallel, activ- ities. 4-Dec-96 Gruninger X to *: The definition of synchronized activit- ies does not depend on real-time event signalling and notification; this only becomes an issue when coordinating agents within an organization.

B.6 STEP ISO 10303-49 (Part 49) Detailed PSL Analysis

	PSL Requirement	Rank	Description			
1	Core Requirements		1			
1.1	Representational Requirements					
1.1.1	ad hoc notes and annotations option- ally associated with any component of a plan - on-the-fly, off-the-cuff notes and documentation. This could be voice, video, as well as text. A person's ob-	\checkmark	The various description properties could be used to capture this informa- tion. Elements such as voice, and video could be related via textual filenames stored in these properties.			
1.1.2	servation of a process might go here. cost data - the cost associated with a resource or task. This could be a fixed cost, cost rate, or a cost derived from other attributes such as duration and level of effort. Costs associated with uncertainty, variability, tolerances, etc	*	We can partially address this by: adding a re- source_property_representation that can describe the cost of the ac- tion_resource_requirement (e.g. dol- lars/hr for a person, etc.).			
1.1.3	level of effort - description of the amount of a resource needed, in any given unit, to accomplish a task. Some example levels of effort are equipment- hour, labor-hour, and crew size.	*	An example: We could setup "crews" as action_resources. I could add an action_resource_requirement that states the requirement, "crew with 10 mem- bers" or "crew with 5 members". Then a requirement_for_action_resource re- flects a satisfying crew.			
1.1.4	product (work item) characteristics- in- formation about an intermediate and fi- nal product which a process will pro- duce.	*	Some aspects of the product can be defined as product_definitions in the product_definition_process.			
1.1.5	resource - a single resource or a group of resources. Some types of resources are equipment, people, information, and in- progress goods.	\checkmark	A resource is defined as an ac- tion_resouce in part 49.			
1.1.6	resource requirement(s) for a task - the relationship between one or more re- sources and a task.	\checkmark	Requirements can be expressed via re- source_property_representations as the value of a resource_property that is part of an action_resource_requirement.			
1.1.7	simple groups of tasks - very basic, high-level set of tasks. One example is the grouping of tasks and sequences that make up a process plan or that make up a phase.	\checkmark	action_method_relationships can be es- tablished to group action_methods in a very basic, high-level set.			
1.1.8	simple resource capabil- ity/characteristics - a high-level description of the characteristics of a resource. More detailed descriptions can be found in the outer core.	V D. Dont /	Descriptions of a resource can be added as resource_properties that are related to a resource.			
	B.6 - STEP, Part 49					

Key:
 \checkmark - Completely satisfies req., * - Partially satisfies req., X - Cannot satisfy req., ? - Uncertain

	PSL Requirement	Rank	Description
1.1.9	simple sequences - linear, time- sequential groups of tasks. More sophisticated relationships such as parallel and alternative tasks can be found in the outer core.	\checkmark	A sequential_method can be defined that assigns a sequence position to each action_method in the grouping.
1.1.10	simple task representation and charac- teristics - a simple, high-level descrip- tion of the task. More detailed rep- resentations can be found in the outer core.	V	actions and action_methods are used to define basic tasks. These basic tasks can be further defined by relating them to a specific product or service that they provide in the manufacturing pro- cess.
1.1.11	task duration - the time required to complete a task or group of tasks. Only simple durations are represented here.	\checkmark	Page 19 of ISO DIS 10303-49 describes the use of the action_property to define the time it takes to perform the task (or any other characteristic). Also see page 28 for action_property_representation.
1.1.12	task executor - who is responsible for executing a task or group of tasks. Ex- amples include a person, controller, or external company if the task is contrac- ted out.	\checkmark	There are a couple of ways to address this requirement in part 49. You can treat the executor in the same way as duration (listed above) or you can define a resource that represents the ex- ecutor and associate it to the task.
1.2	Functional Requirements		
1.2.1	extensibility - there must be a mechan- ism in place to allow a user to add ad- ditional information to the pre-defined data constructs. One such mechanism could be the addition of stubs for user- defined information.	\checkmark	action_properties can be assigned to ac- tion_methods and actions to capture user-defined information intended to extend the information about a task.
1.2.2	resource allocation/deallocation for one or many tasks - the assignment and re- lease of one or more resources to a task of group of tasks. B.6 - STE	*	The support for resource alloca- tion/deallocation is possible, but only at a very high grain. For example: a milling machine can be thought of as being allocated to a task and it will be deallocated once the task has completed, etc. Needs a lower level of support.

	PSL Requirement	Rank	Description
1.2.3	simple precedence - a high-level descrip- tion of the precedence constraints of one task on another. A more detailed de- scription of precedence and constraints can be found in the outer core.	\checkmark	There is the support for ordering con- straints (see simple sequences) as well as informational constraints on the per- formance of tasks. For example, given the example on page 41, we can define exactly when "maintain speed" should follow "drive down street" based on the condition of the light being green. Con- text_dependent_relationship_conditions can be strung together to define the precedence of tasks based on the information in condition_descriptions.
$\frac{2}{21}$	Outer Core Requirements		
2.1 2.1.1	Representational Requirements abstraction - within the scope of this project, there are three concepts of ab- straction that must be captured. (hier- archy, incompleteness, ambiguity)	X	The constructs are very definite and highly structured. They do not permit such things as ranges, abstract levels, etc.
2.1.2	alternative task - (see complex se- quences)	V	In part 49, it is possible to relate actions in a "replacement_relationship" that means that the related_action could be used as an alternate im- plementation of the task. The con- text_dependent_relationship_conditions can also be used to determine which tasks can be alternatively performed, based on some criteria.
2.1.3	associated illustrations and drawings	\checkmark	Part 49 has a unique implement- ation that explicitly incorporates documentation via entities like, ac- tion_method_with_specification_reference and action_method_with_ specifica- tion_reference_constrained.
2.1.4	complex groups of tasks - groups of tasks which have a common tie.	\checkmark	Complexgroupingscanbemadeviathecon-text_dependent_relationship_conditionsandaction_method_to_select_fromentities.
2.1.5	complex resource characteristics - a de- tailed description of the characteristics of a resource or group of resources.	\checkmark	resource_properties and re- source_property_relationships can be defined to describe complex charac- teristics.
	B.6 - STE	P, Part 4	19

	PSL Requirement	Rank	Description
2.1.6	complex sequences - complex ordering relationships between tasks	\checkmark	A variety of entities support the defini- tion of complex sequences: sequential, serial, concurrent, context-dependent. The key entity here is the con- text_dependent_relationship_condition which permits the expression of preconditions of a task.
2.1.7	complex task representation and para- meters - a detailed representation of a task or group of tasks.	\checkmark	Action_properties and ac- tion_property_relationships can be used to express detailed aspects of a task.
2.1.8	concurrent tasks - (see complex se- quences)	\checkmark	concurrent_action_methods can be used for this requirement.
2.1.9	conditional tasks - a task that only needs to be performed under some pre- defined circumstance.	\checkmark	context_depednent_relationship_condition can be defined to model predefined circumstances.
2.1.10	confidence levels - a measure of cer- tainty that some attribute is true.	Х	No support for ranges, or measures of certainty.
2.1.11	constraints - implicit or explicit con- straints associated with a task or re- source.	*	While it could probably be said the con- text_dependent_relationship_conditions represent a type of constraint, as well as the ordering, etc. the support for constraint expression is certainly not enough to say that it completely covers this requirement.
2.1.12	date(s) and time(s) and/or multiple duration(s) - the association of one or more dates and times and/or multiple durations with a resource or task	Х	No support for timepoints, or time in- tervals, etc. This could be listed as an action_property but this temporal sup- port should have stronger core support.
2.1.13	implicit/explicit resource association - an implicit or explicit dependency of a resource on another type of resource.	Х	Cannot find a construct that relates a dependency between two resources, only a resource dependency to an ac- tion or task.
2.1.14	iterative loops - a situation when a task or group of tasks repeats until a desired condition is met	*	This may even be a completely, but there is at least a partially based on the ability to characterize what an action or action_method does, providing precon- ditions via context_dependent_action_ method_relationships, and ordering these tasks to cycle based on some condition (or context).
2.1.15	manual vs. automated tasks - charac- teristics of a task can differ depending on if a human or a machine is perform- ing that task.	*	This could be considered a property of the action (action_property).

	PSL Requirement	\mathbf{Rank}	Description
2.1.16	manufacturing product quantity - the amount of the product that is to man- ufactured.	*	This could again be a property, but it is not well-positioned for use in an application that needs to reason about
			product quantity.
2.1.17	material constraints	*	If materials are manipulated as re- sources to be used in a manufactur- ing process, it would seem possible to express material constraints via ac- tion_resource_requirements.
2.1.18	parallel tasks	*	Unordered, non-related tasks can be thought of as parallel, but greater sup- port is needed to make it completely.
2.1.19	parameters and variables - place hold- ers that can store a constantly changing value.	\checkmark	Supported via the Express language.
2.1.20	pre- and post-processing constraints	*	Since we have conditional tasks, we can express the pre-processing constraints by stating what must be true to execute this task.
2.1.21	queues, stacks, lists - the representation of an ordered or unordered group.	Х	While there are sets, there is no support for these types of data structures.
2.1.22	resource categorization and grouping - a logical grouping of resources with a common tie.	*	Resources with identical "require- ment_for_action_resource" can be thought of as "grouped" by capability.
2.1.23	resource location identification of the location of a resource.	\checkmark	This could be treated as a resource_property or require- ment_for_action_resource depending on its intended use.
2.1.24	resource/task combined characteristics - qualities of a resource that are depend- ent on a particular task, or qualities of a task that are dependent on a particular resource.	Х	I don't think this is supported.
2.1.25	serial tasks	\checkmark	Part 49 has a serial_action_method en- tity to describe this relationship.
2.1.26	state existence constraints	Х	Need smaller grained conditionals to express state representations.
2.1.27	state representations - the description of a process in terms of any combina- tion of the states of the process and/or resource.	X	
2.1.28	temporal constraints	*	High-level constraints for temporal re- lationships. (serial, complex, etc.)
2.1.29	uncertainty/variability/tolerance - the representation of the deviation from the nominal.	Х	No support.
2.2	Functional Requirements		

	PSL Requirement	Rank	Description
2.2.1	ability to insert or attach a highlight (milestones) - the ability for a user to highlight a section of the process	Х	No support for highlighting a section.
2.2.2	complex precedence - the ability to con- vey a series of tasks' ordering require- ments within a given process.	\checkmark	The key here again is the con- text_dependent_relationship_conditions which permit the use of specialized informational requirements.
2.2.3	convey the ancestry or class of a task - the ability to describe a task as it relates to the specialization of another, higher-level task.	X	No hierarchical/decompositional sup- port.
2.2.4	deadline management - the ability to consider a predetermined deadline when making decisions.	X	If we take deadline a deadline to be somehow connected to a date/time rep- resentation than there is no support.
2.2.5	dispatching - the determination and representation of rules and guidelines to decide when items should be released for production.	*	This would have to be partial again since there is a method for condition- ally controlling the applicability of task for a given representation.
2.2.6	eligible resources - the ability to de- termine which resources can be chosen for a task (selection rules)	\checkmark	Resourcescontainrequire-ments_for_action_resourceentriesthat determine this.
2.2.7	exception handling and recovery - the ability to specify corrective action when a task fails.	*	This partly depends on interpretation, but you could imagine adding a condi- tional task after an operative task that would do something in the event that the condition following the operative task fails.
2.2.8	information exchange between tasks - the ability to represent the flow of in- formation among tasks	X	No support.
2.2.9	mathematical and logical operations - the language must be able to perform mathematical and logical operations.	\checkmark	EXPRESS contains math/logic support.
2.2.10	support for task/process templates - the language must allow for templates of a task or process.	Х	No support.
2.2.11	support for simultaneously maintained associations of multiple levels of ab- straction - the ability to associate in- formation at multiple levels of abstrac- tion with a task.	Х	No support.
2.2.12	synchronization of multiple, parallel task sequences - the ability to specify a mechanism to coordinate two or more tasks that occur at the same time.	Х	No support.
	B.6 - STE	P, Part 4	1 49

B.7 O-Plan TF (v.2.3) Detailed PSL Analysis

PSL Requirement 1 Core Requirements 1.1 Representational Requirements	Rank	Description
1.1 Representational Requirements		
1.1.1 ad hoc notes and annotations of ally associated with any compone plan - on-the-fly, off-the-cuff not documentation. This could be	ent of a es and	Notes via comments and "tf info" items. Individual plan items can con- tain "annotation-constraints". Exten- ded documentation for schemas can
video, as well as text. A person servation of a process might go b	n's ob- nere.	be achieved by linking "info" attrib- ute/value pairs with filenames of asso- ciated drawings, etc.
1.1.2 cost data - the cost associated resource or task. This could be cost, cost rate, or a cost derived other attributes such as duratic level of effort. Costs associated uncertainty, variability, tolerance	a fixed d from on and d with	O-Plan TF can be used to describe an action that consumes a resource (e.g. money, in the case of cost). Uncertainty costs, variability, etc. is incorporated by the use of upper/lower bounds on numerical values.
1.1.3 level of effort - description of amount of a resource needed, given unit, to accomplish a task. example levels of effort are equip hour, labor-hour, and crew size.	in any Some	O-Plan TF has a rich set of resource elements that can describe the units, types, and number of resource items that are required by an action.
1.1.4 product (work item) characteri information about an intermedia final product which a process wi duce.	te and	O-Plan TF can be used to model a class of resources that are "producible" when an action is applied. This "produced" item can be an intermediate product that is used to supply a condition for another action.
1.1.5 resource - a single resource or a gradient resources. Some types of resource equipment, people, information, a progress goods.	ces are	O-Plan TF can be used to describe re- sources and resource types.
1.1.6 resource requirement (s) for a tash quantity) - the relationship betwee or more resources and a task.	een one	O-Plan TF resource statements can quantify an action's usage of a resource.
1.1.7 simple groups of tasks - very high-level set of tasks. One ex- is the grouping of tasks and seq that make up a process plan of make up a phase.	cample uences or that	Action schemas can define partially ordered sub-actions and action schemas can be arranged hierarchically through the use of "expands" action patterns.
ity/characteristics - a hig description of the characteristic resource. More detailed descri- can be found in the outer core.		O-Plan TF can give resource charac- teristics that can be used to select the appropriate resource for a task. (e.g. attributing "wolf-proof" characteristics to "bricks" in a sample domain.) 2.3)

Key: $\sqrt{-}$ Completely satisfies req., * - Partially satisfies req., X - Cannot satisfy req., ? - Uncertain

	PSL Requirement	Rank	Description	
1.1.9	simple sequences - linear, time- sequential groups of tasks. More sophisticated relationships such as parallel and alternative tasks can be found in the outer core.	V	O-Plan TF has a number of ways to express temporal relationships. "At" links actions to a specific timepoint. "Duration" specifys a range. TF can also express "delay_between" as a means to specify a latency period between the end and begin of two ac- tions.	
1.1.10	simple task representation and charac- teristics - a simple, high-level descrip- tion of the task. More detailed rep- resentations can be found in the outer core.	\checkmark	Simple high-level descriptions can be attached via the schema annotations that were described in 1.1.1.	
1.1.11	task duration - the time required to complete a task or group of tasks. Only simple durations are represented here.	V	As per Tate (22-Nov): In O-Plan a user can express duration in metric time points against a reference basis of zero time. (e.g. day 45 12:00:00 for example for noon on day 45 of a project.)	
1.1.12	task executor - who is responsible for executing a task or group of tasks. Ex- amples include a person, controller, or external company if the task is contrac- ted out.	√ 	O-Plan TF can select modeled re- sources to be associated with an instan- tiated action. (e.g. selecting vehicles in pacifica sample domain). TF can also be used to directly model the "contract- ing" relationship using [un]supervised conditions.	
1.2	Functional Requirements	,		
1.2.1	extensibility - there must be a mechan- ism in place to allow a user to add ad- ditional information to the pre-defined data constructs. One such mechanism could be the addition of stubs for user- defined information.	\checkmark	O-Plan "other-constraints" can be used to record additional information.	
1.2.2	resource allocation/deallocation for one or many tasks - the assignment and re- lease of one or more resources to a task of group of tasks.	\checkmark	O-Plan TF can be used to model as- signment and release of resources.	
1.2.3	simple precedence - a high-level descrip- tion of the precedence constraints of one task on another. A more detailed de- scription of precedence and constraints can be found in the outer core.	\checkmark	O-Plan TF conditions, effects, and ex- pands can be used to form interschema relationships while orderings are used to define intraschema sub-action rela- tionships.	
2	Outer Core Requirements			
2.1	Representational Requirements			
B.7 - O-Plan TF (v.2.3)				

 2.1.1 abstraction - within the scope of this project, there are three concepts of abstraction that must be captured. (hierarchical fashion can abstract the details of variance) and plan expansions. TF can be arranged into plan levels/phases that allows O-Plan to control how far to plan (incompleteness). More than 1 schema (an be appropriate (ambiguity). 2.1.2 alternative task - (see complex sequences) 2.1.3 associated illustrations and drawings 2.1.4 complex groups of tasks - groups of tasks which have a common tic. 2.1.5 complex resource characteristics - a detailed description of the characteristics of a resource or group of resources. 2.1.6 complex sequences - complex ordering relationships between tasks 2.1.7 complex task representation and parameter s. a detailed representation of a task or group of tasks. 2.1.8 concurrent tasks - (see complex sequences - a detailed representation of a task or group of tasks. 2.1.9 conditional tasks - a task that only needs to be performed under some predefined circumstance. 2.1.9 conditional tasks - a task that only needs to be performed under some predefined circumstance. 2.1.9 conditional tasks - a task that only needs to be performed under some prediction link between their end points." 2.1.9 conditional tasks - a task that only needs to be performed under some prediction link between their group of tasks. 2.1.9 conditional tasks - a task that only needs to be performed under some prediction in the syntam. 2.1.9 conditional tasks - a task that only needs to be performed under some prediction the syntam. 2.1.9 conditional tasks - a task that only needs to be performed under some prediction link between their group on the same tribute is true. 2.1.9 conditional tasks - a task that only needs to be performed under some pred		PSL Requirement	Rank	Description
project, there are three concepts of ab- straction that must be captured. (her- archy, incompleteness, ambiguity) incompleteness. The ab ear- ranged into plan tevels/phases that al- lows O-Plan to control how far to plan (incompleteness). More than 1 schema (and be appropriate (ambiguity)). 2.1.2 alternative task - (see complex se- quences) ✓ More than one TF schema may be ap- propriate for a plan node expansion. 2.1.3 associated illustrations and drawings ✓ Textual items (comments) can be at- tached to O-Plan TF items and exten- ded documentation for the domain can be achieved by linking tf.info attrib- ute/value pairs with filenames of asso- ciated drawings, etc. 2.1.4 complex groups of tasks - groups of tasks which have a common tie. ✓ O-Plan TF can also address constraints related to the overall group. (e.g. de- scribing how much resource an action and its expansions can consume.) 2.1.5 complex resource characteristics - a de- tailed description of the characteristics of a resource or group of resources. ✓ Resources can have a "specific" type that affects how the planning system may use the resource (movable_objects vs. objects, etc.) 2.1.7 complex task representation and para- meters - a detailed representation of a task or group of tasks. ✓ O-Plan TF schema can explicitly rep- resent complex sequences as well as ex- press the elements necessary to create more ordering relationships during gen- erative planning. 2.1.7 complex task representation of a task or group of tasks. ✓ O-Plan TF schema ap	2.1.1		,	
straction that must be captured. (hier- archy, incompleteness, ambiguity) ous plan expansions. TF can be ar- ranged into plan levels/phases that al- lows O-Plan to control how far to plan (incompleteness). More than 1 schema can be appropriate (ambiguity). 2.1.2 alternative task - (see complex se- quences) ✓ More than one TF schema may be ap- propriate for a plan node expansion. 2.1.3 associated illustrations and drawings ✓ Textual items (comments) can be at- tached to O-Plan TF items and exten- ded documentation for the domain can be achieved by linking thinfo attrib- ute/value pairs with filenames of asso- ciated drawings, etc. 2.1.4 complex groups of tasks - groups of tasks which have a common tie. ✓ O-Plan TF can describe an explicit grouping of actions (e.g. install ser- vices). TF can also address constraints related to the overall group. (e.g. de- scribing how much resource an action and its expansions can consume.) 2.1.5 complex resource characteristics - a de- tailed description of the characteristics of a resource or group of resources. ✓ Resources can have a "specific" type that affects how the planning system may use the resource, movable_objects vs. objects, etc.) 2.1.6 complex task representation and para- meters - a detailed representation of a task or group of tasks. ✓ Action schemas can take into ac- count concepts such as applicability during en- erative planning. 2.1.7 complex tasks - (see complex se- quences) ✓ Action schemas can take into ac- count concepts such as applicability		-	v	0
archy, incompleteness, ambiguity) ranged into plan levels/phases that allows O-Plan to control how far to plan tincompleteness). More than 1 schema can be appropriate (ambiguity). 2.1.2 alternative task - (see complex sequences) ✓ More than one TF schema may be appropriate (ar appropriate for a plan node expansion. 2.1.3 associated illustrations and drawings ✓ Textual items (comments) can be attached to O-Plan TF items and extended documentation for the domain can be achieved by linking tinfo attribute/value pairs with filenames of associated drawings, etc. 2.1.4 complex groups of tasks - groups of tasks which have a common tie. ✓ O-Plan TF can describe an explicit grouping of actions (e.g. install services). TF can also address constraints related to the overall group. (e.g. describing how much resource an action and its expansions can consume.) 2.1.5 complex resource characteristics - a detailed description of the characteristics of a resource or group of resources. ✓ Resources can have a "specific" type reset complex sequences - complex ordering relationships between tasks 2.1.6 complex task representation and parameters - a detailed representation of a task or group of tasks. ✓ Action schemas can take into account concepts such as applicability (only use if), performance limits (time windows, resource constraints on its conditions, suitable parameter bindings, etc. 2.1.6 complex task representation of a quences) ✓ Action schemas can take into account concepts such as applicability (only use if),				
2.1.2 alternative task - (see complex sequences) ✓ More than one TF schema may be appropriate (ambiguity). 2.1.3 associated illustrations and drawings ✓ More than one TF schema may be appropriate (arbiguity). 2.1.3 associated illustrations and drawings ✓ More than one TF schema may be appropriate (arbiguity). 2.1.4 complex groups of tasks - groups of tasks which have a common tie. ✓ OPlan TF can describe an explicit grouping of actions (e.g. install services). TF can also address constraints related to the overall group. (e.g. describing how much resource an action and its expansions can consume.) 2.1.5 complex resource characteristics - a detailed description of the characteristics of a resource or group of resources. ✓ O-Plan TF schemas can explicit yreptes the dements necessary to create more ordering relationships between tasks 2.1.6 complex task representation and parameters - a detailed representation of a task or group of tasks. ✓ O-Plan TF schemas can take into account concepts such as applicability (only_uscif), performance limits (time windows, resource consumption), and a number of constraints on its conditions, suitable parameter bindings, etc. 2.1.8 concurrent tasks - (see complex seq quences) ✓ Action schemas can take into account concepts such as applicability (only_uscif), performance limits (time windows, resource consumption), and a number of constraints on its conditions, suitable parameter bindings, etc. 2.1.8				
2.1.2 alternative task - (see complex sequences) ✓ More than one TF schema may be appropriate (ambiguity). 2.1.3 associated illustrations and drawings ✓ Textual items (comments) can be athended to O-Plan TF items and extended to O-Plan TF items and extended documentation for the domain can be achieved by linking tLinfo attribute/value pairs with filenames of associated drawings, etc. 2.1.4 complex groups of tasks - groups of tasks which have a common tie. ✓ O-Plan TF can describe an explicit grouping of actions (e.g. install services). TF can also address constraints related to the overall group. (e.g. des scribing how much resource an action and its expansions can consume.) 2.1.5 complex resource characteristics - a det tailed description of the characteristics of a resource or group of resources. ✓ Resources can have a "specific" type tract after to the overall group. (e.g. des scribes during system may use the resource. (movable_objects vs. objects, etc.) 2.1.6 complex task representation and parameters - a detailed representation of a task or group of tasks. ✓ O-Plan TF schemas can explicitly represent ecomplex sequences as well as express the elements necessary to create more ordering relationships during generative planning. 2.1.8 concurrent tasks - (see complex see quences) ✓ Action schemas can take into achieves a sublicability (only_useif), performance limits (time windows, resource consumption), and a number of constraints on its conditions, suitable parameter bindings, etc. 2.1.8 concurren				
2.1.2 alternative task - (see complex sequences) ✓ More than one TF schema may be appropriate for a plan node expansion. 2.1.3 associated illustrations and drawings ✓ Textual items (comments) can be attached to O-Plan TF tems and extended documentation for the domain can be achieved by linking tf.info attribute/value pairs with filenames of associated drawings, etc. 2.1.4 complex groups of tasks - groups of tasks which have a common tie. ✓ O-Plan TF can describe an explicit grouping of actions (e.g. install services). TF can also address constraints related to the overall group. (e.g. describing how much resource an action and its expansions can consume.) 2.1.5 complex resource characteristics - a detailed description of the characteristics of a resource or group of resources. ✓ Resources can have a "specific" type that affects how the planning system may use the resource. (movable_objects vs. objects, etc.) 2.1.6 complex sequences - complex ordering relationships between tasks ✓ O-Plan TF schemas can explicity represes the elements necessary to create more ordering relationships during generative planning. 2.1.6 complex task representation and parameter bindings, etc. ✓ O-Plan TF schemas can take into account concepts such as applicability (only.use:f), performance limits (time windows, resource consumption), and a number of constraints on its conditions, suitable parameter bindings, etc. 2.1.7 complex task representation of a task or group of tasks. ✓ O-Nov-90 via Tate				=
2.1.2 alternative task - (see complex sequences) ✓ More than one TF schema may be appropriate for a plan node expansion. 2.1.3 associated illustrations and drawings ✓ Textual items (comments) can be attached to O-Plan TF items and extended documentation for the domain can be achieved by linking tf.info attribute/value pairs with filenames of associated drawings, etc. 2.1.4 complex groups of tasks - groups of tasks which have a common tie. ✓ O-Plan TF can describe an explicit grouping of actions (e.g. install services). TF can also address constraints related to the overall group. (e.g. describe in a resource or group of resources. 2.1.5 complex resource characteristics of a resource or group of resources. ✓ Resources can have a "specific" type that affects how the planning system may use the resource. (movable.objects vs. objects, etc.) 2.1.6 complex task representation and parameters - a detailed representation of a task or group of tasks. ✓ O-Plan TF schemas can take into account concepts such as applicability (only_use.ff), performance limits (time windows, resource consumption), and a number of constraints on its conditions, suitable parameter bindings, etc. 2.1.9 conditional tasks - a task that only needs to be performed under some prediction link between their begin points. ✓ TF schema filters (only.use.ff) control the applicability of a specific schema. 2.1.9 conditional tasks - a task that only needs to be performed under some prediction link between their begin points. ✓				
quences) propriate for a plan node expansion. 2.1.3 associated illustrations and drawings ✓ Textual items (comments) can be attached to O-Plan TF items and extended documentation for the domain can be achieved by linking tLinfo attribute/value pairs with filenames of associated drawings, etc. 2.1.4 complex groups of tasks - groups of tasks which have a common tie. ✓ O-Plan TF can describe an explicit grouping of actions (e.g. install services). TF can also address constraints related to the overall group. (e.g. describing how much resource an action and its expansions can consume.) 2.1.5 complex resource characteristics of a resource or group of resources. ✓ Resources can have a "specific" type that affects how the planning system may use the resource. (movable.objects vs. objects, etc.) 2.1.6 complex task representation and parameters - a detailed representation of a task or group of tasks. ✓ O-Plan TF schemas can explicity repress the elements necessary to create more ordering relationships during generative planning. 2.1.7 complex task representation of a task or group of tasks. ✓ O-Plan TF schemas can take into account concepts such as applicability (only_use_if), performance limits (time windows, resource consumption), and a number of constraints on its conditions, suitable parameter bindings, etc. 2.1.8 concurrent tasks - (see complex sequences are duration link between their begin points and the same zero duration link between their end points." 2.1.9 conditional tasks - a t	2.1.2	alternative task - (see complex se-		
2.1.4 complex groups of tasks - groups of tasks which have a common tie. ✓ O-Plan TF can also address constraints related to the overall group. $\mathbf{D} \cdot \mathbf{I} = \mathbf{O} - \mathbf{\Gamma} \operatorname{Iafi} \mathbf{I} \mathbf{\Gamma} (V. 2.3)$			n TF (v.:	

	PSL Requirement	Rank	Description
2.1.11	constraints - implicit or explicit con- straints associated with a task or re- source.	\checkmark	O-Plan has a rich set of constraint types to limit the plan behavior (this includes actions and resource usage).
2.1.12	date(s) and time(s) and/or multiple duration(s) - the association of one or more dates and times and/or multiple durations with a resource or task	\checkmark	O-Plan TF can be used to express relat- ive temporal relationships that are tied to an initial zero date/time.
2.1.13	implicit/explicit resource association - an implicit or explicit dependency of a resource on another type of resource.	Х	There are no dependency relationships between resource types in O-Plan TF.
2.1.14	iterative loops - a situation when a task or group of tasks repeats until a desired condition is met	Х	While the use of an "iterate" or "foreach" node type is planned, TF ver- sion 2.3 does not contain this function- ality. (Now in O-Plan version 1 January 1997.)
2.1.15	manual vs. automated tasks - charac- teristics of a task can differ depending on if a human or a machine is perform- ing that task.	\checkmark	Separate action schemas can be de- signed with constraints on agent bind- ing types. If a schema is instanit- ated with an agent binding of type "machine" there will be a certain seq. whereas the type "human" schema would be different.
2.1.16	manufacturing product quantity - the amount of the product that is to man- ufactured.	\checkmark	The amount of product to be produced can be expressed as an achieve condi- tion in a task schema and the action schemas can be designed to "produce" the resource based on constraints.
2.1.17	material constraints	*	Materials can be qualified through the use of resource types and "always" as- sertions. (e.g. bricks are wolf-proof, etc.)
2.1.18	parallel tasks	\checkmark	O-Plan actions are arranged in a par- tially ordered fashion that can repres- ent parallel tasks.
2.1.19	parameters and variables - place hold- ers that can store a constantly changing value.	\checkmark	O-Plan plan state variables can be used to bind values to various aspects of the plan.
2.1.20	pre- and post-processing constraints	\checkmark	This is achieved through the use of O- Plan conditions (pre) and effects (post).
2.1.21	queues, stacks, lists - the representation of an ordered or unordered group.	*	O-Plan TF utilizes "sets" but does not have specific data structures such as queues or stacks.
2.1.22	resource categorization and grouping - a logical grouping of resources with a common tie.	\checkmark	Logical resource grouping is created by using specific resource types.
	B.7 - O-Pla	n TF (v.:	2.3)

	PSL Requirement	Rank	Description
2.1.23	resource location identification of the	\checkmark	The "pacifica" TF sample shows how
	location of a resource.		resource location can be represented us-
			ing an "at $OBJ = LOC$ ".
2.1.24	resource/task combined characteristics		The simplest way to address this re-
	- qualities of a resource that are depend-	v	quirement is to create alternate action
	ent on a particular task, or qualities of a		schemas that utilize different resources
	task that are dependent on a particular		and can also thereby have different time
	resource.		constraints.
2.1.25	serial tasks	/	O-Plan TF can be used to impose a
2.1.20	Serial tasks	\checkmark	total ordering between actions where
			0
0.1.00	· · · ·	,	necessary.
2.1.26	state existence constraints	\checkmark	This requirement can be expressed in
			detail by selecting an appropriate con-
			dition type in O-Plan TF.
2.1.27	state representations - the description	\checkmark	O-Plan uses a state-based approach for
	of a process in terms of any combina-		plan domain representations (I.e. con-
	tion of the states of the process and/or		ditions and effects relative to a world
	resource.		state)
2.1.28	temporal constraints		Time "windows" can be expressed for
	-	v	actions in O-Plan TF.
2.1.29	uncertainty/variability/tolerance - the		Numerical variables can be represented
	representation of the deviation from the	v	via Min/Max pairs and a "computed"
	nominal.		value that must lie within this range.
	nommai.		This allows for tolerance and variability
			of a value.
0.0	Functional Requirements		or a varue.
2.2	Functional Requirements	*	
2.2.1	ability to insert or attach a highlight		As per Tate: O-Plan can support the
	(milestones) - the ability for a user to		attachment of milestones or statements
	highlight a section of the process		(effects) about some point in the plan.
			But the ability to "highlight" or annot-
			ate some area of the plan is outside of
			what TF is trying to do.
2.2.2	complex precedence - the ability to con-	\checkmark	O-Plan action orderings can be spe-
	vey a series of tasks' ordering require-		cified within an action schema or im-
	ments within a given process.		plied through the conditions and ef-
			fects.
2.2.3	convey the ancestry or class of a task		The "expands" entry in an action
	- the ability to describe a task as it	v	schema denotes how it extends a higher
	relates to the specialization of another,		level action.
	higher-level task.		
2.2.4	deadline management - the ability		O-Plan can handle tasks with relative
2.2.4	to consider a predetermined deadline	V	
	-		time constraints, durations, etc.
0.0 5	when making decisions.	,	
2.2.5	dispatching - the determination and	\checkmark	The preconditions of an action can be
	representation of rules and guidelines to		utilized as a mechanism for stating dis-
	decide when items should be released		patching rules.
	for production.		
	B.7 - O-Pla	n TF (v.2)	2.3)

	PSL Requirement	Rank	Description		
2.2.6	eligible resources - the ability to de-	\checkmark	In O-Plan TF, conditions on using re-		
	termine which resources can be chosen		sources can be defined that meet this		
	for a task (selection rules)		requirement.		
2.2.7	exception handling and recovery - the	*	Alternative schemas (and orderings)		
	ability to specify corrective action when		can be chosen to satisfy a task when		
	a task fails.		a suggested course of action fails.		
2.2.8	information exchange between tasks -	\checkmark	Information is "passed" between ac-		
	the ability to represent the flow of in-		tions via plan state variables.		
	formation among tasks				
2.2.9	mathematical and logical operations -	\checkmark	O-Plan TF can be used to express the		
	the language must be able to perform		necessary mathematical and logical op-		
	mathematical and logical operations.		erations for this requirement.		
2.2.10	support for $task/process$ templates -	\checkmark	via Tate (22-Nov): All Task Formal-		
	the language must allow for templates		ism schemas are "generic processes" or		
	of a task or process.		"task descriptions" that meet this re-		
			quirement.		
2.2.11	support for simultaneously maintained	\checkmark	Constraints can be attached at any level		
	associations of multiple levels of ab-		of an action hierarchy that would be ap-		
	straction - the ability to associate in-		propriate for that schema.		
	formation at multiple levels of abstrac-				
	tion with a task.				
2.2.12	synchronization of multiple, parallel	\checkmark	See 2.1.8.		
	task sequences - the ability to specify				
	a mechanism to coordinate two or more				
	tasks that occur at the same time.				
	B.7 - O-Plan TF (v.2.3)
